22 Running Head: Thrombin/PAR-1 mediated endothelial damages in GDM

23 **Abbreviations**

24	AGEs	advanced glycation endproducts
25	AG	aminoguanidine
26	Arg	argathroban
27	DM	diabetes mellitus
28	ELISA	enzyme-linked immunosorbent assay
29	HG	high glucose
30	HUVECs	human umbilical vein endothelial cells
31	IL	interleukin
32	GDM	gestational diabetes mellitus
33	LDH	lactate dehydrogenase
34	NLRP1	nucleotide-binding domain and leucine-rich repeat containing protein 1
35	PAR-1	protease-activated receptor 1
36	qPCR	real-time fluorescence quantitative PCR
37	RAGE	receptor for advanced glycation endproducts
38	Sar	sarsasapogenin
39	shRNA	short hairpin RNA
40	Vor	vorapaxar

42 **Abstract**

43 Gestational diabetes mellitus (GDM) is associated with an increased risk of progressing to type 2
44 DM and cardiovascular disease; however, the pathogenesis is still poorly understood. This study
45 was to investigate roles of thrombin and its receptor protease-activated receptor 1 (PAR-1) and
46 NLRP1 inflammasome in endothelial injury in GDM condition. Umbilical cord and plasma of
47 GDM patients and high glucose (HG) cultured human umbilical vein endothelial cells (HUVECs)
48 were used to examine the pathological changes of these pathways. Meanwhile, ameliorative
49 effects and potential mechanisms of a natural product sarsasapogenin (Sar) were investigated in
50 HUVECs. Thrombin/PAR-1 pathway, advanced glycation endproducts (AGEs) and their receptor
51 (RAGE) axis, and the nucleotide-binding domain and leucine-rich repeat containing protein 1
52 (NLRP1) inflammasome were activated in GDM condition and HG-cultured HUVECs,
53 accompanied by endothelial injury (decreased cell viability and increased lactate dehydrogenase
54 release). Nevertheless, thrombin inhibition or PAR-1 antagonism caused decreases in AGEs
55 formation and RAGE expression in HG-cultured HUVECs, while AGEs inhibition or RAGE
56 antagonism declined PAR-1 expression not thrombin activity. Furthermore, thrombin inhibition or
57 PAR-1 antagonism restrained NLRP1 inflammasome activation in HG-cultured HUVECs;
58 meanwhile, NLRP1 expression and interleukin 18 levels were remarkably reduced in HG-cultured
59 HUVECs after PAR-1 knockdown. Interestingly, Sar co-treatment could suppress
60 thrombin/PAR-1 pathway, NLRP1 inflammasome, and AGEs/RAGE axis. Together, endothelial
61 damages in GDM were likely due to enhanced interaction between AGEs/RAGE axis and
62 thrombin/PAR-1 pathway, followed by NLRP1 inflammasome activation. Moreover, Sar may act
63 as a protective agent against endothelial injury in chronic HG condition.

64

66 inflammasome; AGEs/RAGE axis; sarsasapogenin

Journal Pre-proofs

68 1. Introduction

69 Gestational diabetes mellitus (GDM) is a disease of abnormal glucose tolerance during pregnancy,
70 which is accompanied by a series of adverse responses in pregnant women [1], subsequently
71 leading to fetal macrosomia, respiratory distress syndrome, and type 2 diabetes in the offspring
72 [2]. Although abnormal glucose tolerance usually returns to normal in the immediate postpartum
73 period, women with GDM have a 20-70% risk of progressing to type 2 diabetes in the first decade
74 after delivery [3]. However, at present, the mechanisms of how GDM develops type 2 diabetes are
75 still unclear. Thus, it is important to deeply clarify the biochemical pathways in GDM. Moreover,
76 pharmacological interventions might prevent or delay the onset of type 2 diabetes in the affected
77 women.

78 Physiological changes of blood coagulation occur and might be at a prothrombotic state in
79 normal pregnancy, especially in middle and late stages [4]. Simultaneously patients with diabetes
80 are in a systemic and chronic blood hypercoagulability condition due to hypercoagulation and
81 platelet activation [5]. Therefore, GDM may aggravate the changes of blood coagulation in normal
82 pregnancy [6, 7]. Thrombin, a serine protease produced during intravascular coagulation, is
83 typically regarded as a consequence of vascular injury, and protease-activated receptors (PARs)
84 mediate the effects of thrombin in normal and disease states [8]. Vascular endothelial injury and
85 chronic low-grade inflammation have been considered central points in the pathophysiology of
86 GDM [9-11]. Elevated levels of inflammatory mediators may be associated with an increased
87 coagulability and a tendency towards thrombus formation in patients with type 2 diabetes who
88 have microvascular complications [12], suggesting an interaction between inflammation and blood
89 coagulation system [5]. Thrombin and PAR-1, a prototypical receptor of thrombin, also play

90 important roles in vascular physiology and inflammation [13-15]. Ishibashi et al. report that
91 advanced glycation endproducts (AGEs), key factors for diabetic complications in
92 microangiopathy, potentiate the citrated plasma-induced oxidative and inflammatory reactions in
93 endothelial cells via the activation of thrombin/PAR-1 system [16]. Early reports show that
94 proinflammatory effect of thrombin and PAR-1 is associated with NF-kappaB activation [17, 18],
95 while interleukin 1 β (IL-1 β) enhances granzyme B-mediated neurotoxicity by increasing PAR-1
96 expression [19]. Moreover, a recent report indicates that high glucose induced endothelial injury is
97 associated with NLRP3 inflammasome activation in human umbilical vein endothelial cells
98 (HUVECs) [20]. Thus, inflammatory responses caused by thrombin/PAR-1 pathway may involve
99 the activation of NLRP3/1 inflammasome besides NF-kappaB activation in endothelium.
100 However, it is not clear about the role of thrombin and PAR-1 signaling in high glucose-caused
101 endothelial damages in GDM condition, and the relationship of thrombin/PAR-1 pathway and
102 NLRP1 inflammasome activation is not understood in vascular endothelial cells.

103 Sarsasapogenin (Sar) is a major steroidal sapogenin of the timosaponins separated from the
104 Chinese Materia Medica *Rhizoma Anemarrhenae* (family Asparagaceae). Timosaponin AIII and
105 BII, the common glycosides of Sar, are reported to show significant antiplatelet, antithrombotic
106 effects and anti-inflammatory actions [21, 22], indicating that timosaponins and the major aglycon
107 Sar have anticoagulation and antithrombotic effects [23-25]. Importantly, timosaponin AIII and
108 Sar ameliorate colitis in mice, and the vitro and in vivo anti-inflammatory effects of Sar are more
109 potent than AIII [26]. In addition, a recent report from our team showed that Sar markedly
110 ameliorated diabetic nephropathy in rats via inhibiting NLRP3 inflammasome activation and
111 AGEs/RAGE interaction [27]. Thus, anti-inflammatory effects may contribute to the

112 anticoagulation and antithrombotic effects of timosaponins and Sar, and Sar may be a good
113 candidate for protection of the vascular endothelium.

114 In this study, our aims were: firstly, whether thrombin/PAR-1 pathway and the NLRP1
115 inflammasome were activated in GDM patients and HUVECs cultured with high glucose;
116 secondly, whether activated thrombin/PAR-1 resulted in the activation of NLRP1 inflammasome;
117 thirdly, whether enhanced AGEs/RAGE interaction mediated the activated thrombin/PAR-1
118 signaling in HUVECs in high glucose condition; finally, whether a natural compound Sar
119 ameliorated the damaged vascular endothelium in high glucose-cultured HUVECs.

120 2. Materials and Methods

121 2.1. Human specimen collection

122 GDM was diagnosed according to the International Association of the Diabetes and Pregnancy
123 Study Group (IADPSG) criteria: The pregnant women with 24-28 weeks were subjected to oral
124 glucose tolerance test by using 75 g glucose; then those patients were diagnosed to GDM with any
125 of the following results: fasting plasma glucose ≥ 5.1 mmol/L, 1 h plasma glucose ≥ 10.0
126 mmol/L, and 2 h plasma glucose ≥ 8.5 mmol/L [28]. The high blood glucose in GDM patients
127 was controlled using diet or insulin. For insulin control, the blood glucose was kept within 4.4
128 mmol/L after fasting or at 6.7 mmol/L for 2 hour post-meal. The umbilical cord tissues of
129 pregnant women with and without GDM hospitalized in full-term pregnancy were collected in the
130 cesarean section operating room of the Affiliated Hospital of Xuzhou Medical University. The
131 umbilical cord tissue 2 to 3 cm near the fetus side was cut and collected, one part for paraffin
132 embedding and the other part preserved in the -80°C refrigerator for use. Serum samples were
133 collected from the Department of Clinical Laboratory of the Affiliated Hospital of Xuzhou

134 Medical University. The experiment obtained an approval from the Ethics Committee of the
135 Affiliated Hospital of Xuzhou Medical University (reference number: XYFY2019-KL172-02).

136 2.2. HUVECs culture and treatments

137 The HUVECs cell line was purchased from Shanghai Bioengineering Biotechnology Co., Ltd,
138 China. HUVECs cultured in vitro at passage 5 to 10 were used for experiments. The cells were
139 cultured in Dulbecco's modified Eagle medium (DMEM) containing 10% fetal bovine serum.
140 DMEM culture medium and fetal bovine serum were purchased from Hyclone (Logan, UT, USA).
141 After incubation for 24 h under normal conditions (medium containing 5.56 mmol/L glucose, 10%
142 FBS, 100 U/mL penicillin and 100 µg/mL streptomycin, 5% CO₂, 37 °C) and subsequent cell
143 cycle synchronization for 12 h, HUVECs were divided into the following groups: normal glucose
144 group (NG, 5.56 mmol/L glucose), high glucose group (HG, 30 mmol/L glucose), low, middle,
145 and high concentrations of Sar group (HG+Sar, 30 mmol/L glucose plus 0.2, 1.0, 5.0 µmol/L
146 sarsasapogenin, respectively), PAR-1 antagonist group (HG+Vor, 30 mmol/L glucose plus 1.0
147 µmol/L vorapaxar), thrombin inhibitor group (HG+Arg, 30 mmol/L glucose plus 1.0 µmol/L
148 argatroban), AGEs inhibitor group (HG+AG, 30 mmol/L glucose plus 1.0 µmol/L
149 aminoguanidine), and RAGE antagonist group (HG+FPS-ZM1, 30 mmol/L glucose plus 1.0
150 µmol/L FPS-ZM1). Sarsasapogenin (purity > 98%) was purchased from Beijing Medicass
151 Biotechnologies, Co. Ltd., China, vorapaxar d from Selleckchem (Shanghai), argatroban from
152 Sigma-Aldrich (Shanghai), aminoguanidine from Aladdin (Shanghai), and FPS-ZM1 from
153 MedChemExpress (Shanghai), China. Sarsasapogenin and all the above tool drugs were dissolved
154 in dimethylsulfoxide and made into stock solutions for use. After treatment with the above
155 different agents for 48 h, the cells were harvested for indices analysis. The culture time was

156 selected according to the changes of PAR-1 protein in HUVECs cultured with 30 mmol/L glucose
157 for 24 h, 48 h, and 72 h, respectively.

158 2.3. PAR-1 knockdown in HUVECs

159 Lentivirus carrying F2R shRNA (shF2R) (Shanghai Genechem Gene Chemical Technology, Co.
160 Ltd., China) was transfected into HUVECs, establishing a stable cell line with PAR-1 knockdown.
161 After 72 h of screening with puromycin (Xuzhou VICMED Bioengineering Co., Ltd., China),
162 samples of cell stable strains were collected. Then the interference efficiency of shF2R was
163 confirmed, and the cells were divided into two kinds: negative control (shNC) and PAR-1
164 knockdown (shF2R). The specific groups were: HG group (30 mmol/L glucose), HG+Sar group
165 (30 mmol/L glucose plus 5 μ mol/L Sar), shF2R+HG group (30 mmol/L glucose in shF2R cells),
166 and shF2R+HG+Sar, (30 mmol/L glucose plus 5 μ mol/L in shF2R cells). The protein expression
167 of NLRP1 was detected by Western blot and intracellular IL-18 level by enzyme-linked
168 immunosorbent assay (ELISA).

169 2.4. CCK-8 assay for cell viability

170 CCK-8 assay was used for cell damage [29]. Briefly, cell suspension (100 μ L/well, 1.0×10^6 /ml)
171 was pre-incubated in a 96-well plate for 24-48 h at 37°C in a humidified atmosphere of 5% CO₂.
172 After the cells were incubated in different groups for 24 h, 10 μ L of the CCK-8 solution (Dongren
173 Chemical Technology (Shanghai) Co. Ltd., China) was added to each well of the plate and
174 incubated for 2 h in incubator. After 10 μ L of 1% (w/v) SDS added to each well in dark at room
175 temperature, the absorbance was determined at 450 nm using a microplate reader. The net
176 absorbance of the normal glucose group was considered as 100% of the cell viability.

177 2.5. Lactate dehydrogenase (LDH) release for cytotoxicity

178 LDH release was used to further assess endothelial cell injury referring to previous report [30].
179 Add 100 μL of cell suspension to each well in 96-well plate, mix and prepare in culture incubator
180 (37°C , 5% CO_2) for 24 h. One hour before the scheduled detection time point, the cell culture
181 plate was taken out from the cell culture incubator, and the reagent provided by the LDH release
182 kit (Beyotime Biotechnology, Nantong, China) was added to the “control well with maximum
183 enzyme activity”. After adding the reagents of LDH release, mix repeatedly and continue to
184 incubate in the cell culture incubator. After the predetermined time was reached, the cell culture
185 plates were centrifuged at 400 g for 5 min. Then 120 μL of the supernatant was taken and added to
186 the corresponding well in a new 96-well plate, and then 60 μL of test solution of LDH release was
187 added, mixed well, and incubated at room temperature for 30 min in the dark. The absorbance was
188 then measured at 490 nm. The net absorbance of the normal glucose group was considered as
189 100% of the LDH release.

190 2.6. Determination of thrombin activity

191 Thrombin activity was measured by a fluorometric assay based on the cleavage rate of the
192 synthetic thrombin substrate Boc-Asp (OBzl)-Pro-Arg-AMC according to previous study [31].
193 The protein concentration in the supernatant of tissues or cells was determined by the BCA
194 method. Tris/HCL 1.21 g, CaCl_2 22.2 mg, NaCl 1.755 g, and BSA 0.2 g were dissolved in 200 mL
195 of deionized water (pH = 8.8) to prepare a buffer solution, which was stored at 4°C until use. The
196 77 mg Boc-Asp (OBzl)-Pro-Arg-AMC fluorogenic substrate (Nanjing Peptide Industry
197 Biotechnology Co., Ltd, China) was dissolved in 10 mL of DMSO, and 1.0 mg bestatin
198 (Selleckchem, Shanghai, China) in 1 mL DMSO, mixed well in dark, and stored at -20°C .
199 According to protein amount of 60 μg , the enzymatic sample was added to the reaction system

200 with a final volume 100 μ L including bestatin and the fluorescent substrate in a black 96-well
201 microplate, and then fully mixed. The reaction was carried out in an oven at 37 °C for 50 min, and
202 the optical density value was immediately measured with a fluorescence spectroscopy at the
203 excitation wavelength 360 nm and emission wavelength 465 nm. The net absorbance from the
204 plates of cells cultured with normal glucose was considered as 100% thrombin activity.

205 2.7. ELISA assay of IL-18 and IL-1 β

206 IL-18 and IL-1 β levels were measured by using corresponding human IL-18 and IL-1 β ELISA kits
207 (Wuhan Boster Bio-technology Co., Ltd., China) according to the manufacturer's instructions.

208 2.8. Western blotting analysis for PAR-1, cleaved-caspase-1, NLRP1, and RAGE levels

209 Protein concentration of the sample was determined using a BCA protein assay kit (Thermo
210 Scientific, Rockford, IL, USA). The protein samples were separated using sodium dodecyl sulfate
211 polyacrylamide gel electrophoresis and transferred to polyvinylidene fluoride membrane
212 (Millipore, Bedford, MA, USA). The membrane was blocked with 2% milk powder solution for
213 60 min and incubated over night at 4°C with primary antibodies anti- β -actin (Bioworld
214 Technology, Inc., St. Louis, USA, 1:1000), anti-RAGE (Abcam Company, Cambridge, UK,
215 1:1000), anti-PAR-1 (Sigma-Aldrich Company, Shanghai, China, 1:1000), anti-cleaved-caspase-1
216 (Bioworld Technology, Inc., Bloomington, USA, 1:1000), and anti-NLRP1 (Abcam Company,
217 Cambridge, USA, 1:1000). The proteins were detected using goat anti rabbit IgG(H+L) secondary
218 antibodies (Li-Cor Inc., Lincoln, NE), respectively. Infrared Imaging System (Gene Company
219 Limited, Hong Kong, China) was applied to detect immunoreactive blots. The signal densities on
220 the blots were measured with Image J software and normalized using rabbit anti- β -actin antibody
221 (Bioworld Technology, St. Louis, USA) or rabbit anti-GAPDH antibody (ABclonal

222 Biotechnology Co., Ltd., Boston, USA) as an internal control.

223 2.9. Immunofluorescence analysis for PAR-1 and AGEs

224 Immunofluorescence assay was performed according to the report [32]. Cells plated on coverslips
225 were fixed with 4% paraformaldehyde for 15 min, permeabilized with 0.1% TritonX-100 in PBS
226 for 5 min, treated with blocking medium (1% bovine serum albumin in PBS) for 30 min, and then
227 incubated with anti-PAR-1 antibody (Cat No.Cleaved-Ser42, Sigma-Aldrich Company, Shanghai,
228 China) or anti-AGEs antibody (Abcam Company, Cambridge, UK), at 37°C for 2 h.

229 Immune-reacted primary antibody was detected after 1-h incubation in dark place at 37°C with a
230 secondary antibody Dylight 594 Affinipure donkey anti-rabbit IgG (H+L) (Earthox, Millbrae, CA,
231 USA).The cells were further stained with DAPI (Vector, Burlingame, CA, USA) for 2 min in dark
232 place at room temperature and washed, then mounted onto microscope slides in mounting
233 medium. Observations were carried out by using an Olympus BX43F fluorescence microscope
234 (Tokyo, Japan).

235 2.10. AGEs expression in umbilical cord by immunofluorescence

236 Protein detection in tissue paraffin section by immunofluorescence assay was conducted as our
237 previous report [27]. Briefly, 4- μ m sections were incubated with anti-AGEs antibody (Abcam
238 Company, Cambridge, UK, 1:200) overnight at 4 °C followed by the secondary antibody Dylight
239 594-AffiniPure donkey anti-rabbit IgG(H+L) (EarthOx, LLC, Millbrae, USA). Then, the sections
240 were further stained with DAPI (Vector, Burlingame, USA) for 3 min in dark place. Finally, the
241 sections were examined using an Olympus BX43F fluorescence microscope (Tokyo, Japan).

242 2.11. Statistical analysis

243 All statistical analyses were carried out using GraphPad Prism 7.0 software. The values (a

244 maximum of two) with a large dispersion to the mean were rejected during data entry. An
245 unpaired, two-tailed Student's *t* test was performed for statistical analysis or one-way ANOVA
246 with Dunnet's post hoc tests for analysis, wherever applicable. Data were represented as mean \pm
247 SEM. A *P* value < 0.05 was considered statistically significant.

248 **3. Results**

249 3.1. Activation of the thrombin/PAR-1 pathway and AGEs/RAGE axis in GDM patients

250 To determine whether the thrombin/PAR-1 pathway was activated in GDM patients, thrombin
251 activity and protein expression of PAR-1 were assessed in umbilical cord. The data indicated that
252 enzymatic activity of thrombin and protein expression of PAR-1 were significantly (both *P* $<$
253 0.01) increased in the umbilical cord of GDM women, compared with those in normal pregnant
254 women (Fig. 1A, B). Meanwhile, further to investigate the alteration of AGEs/RAGE axis in
255 GDM condition, AGEs levels and protein expression of RAGE were determined in the GDM
256 women. It was found that protein expression of RAGE (*P* < 0.01) as well as AGEs levels was
257 markedly up-regulated in the umbilical cord of GDM women, compared with the normal pregnant
258 women (Fig. 1C, D). These results indicated that both thrombin/PAR-1 pathway and AGEs/RAGE
259 axis were activated in vascular endothelium in GDM condition.

260 3.2. Activation of the NLRP1 inflammasome in GDM patients

261 In order to explore whether activation of the NLRP1 inflammasome occurred in GDM patients,
262 protein expression of NLRP1 and cleaved-caspase 1 (two major components of the NLRP1
263 inflammasome) in umbilical cord, and an important product IL-18 levels in plasma were
264 examined. GDM significantly (*P* < 0.05 or *P* < 0.01) raised the protein expressions of NLRP1 and
265 cleaved-caspase 1 in umbilical cord as well as IL-18 levels in plasma of the expectant women,

266 compared with the normal expectant mothers (Fig. 2A, B, C). However, it was found that IL-1 β
267 levels were very low in plasma of GDM patients (data not shown). So the NLRP1 inflammasome
268 was activated in GDM condition.

269 3.3. Activation of the thrombin/PAR-1 pathway in HG-cultured HUVECs and effects of Sar

270 To thoroughly investigate the changes of those pathways in GDM condition, HG-cultured
271 HUVECs (a cell line of endotheliocyte) was used. Protein expression of PAR-1 was selected to be
272 examined in HUVECs cultured with high glucose for different time to seek for applicable culture
273 protocol. It was found that 30 mmol/L glucose obviously increased the protein expression of
274 PAR-1 in HUVECs after culture for both 48 h and 72 h by immunofluorescence analysis, while
275 PAR-1 protein was slightly raised for 24 h culture (Fig. 3). So the in vitro experiment protocol
276 HUVECs cultured with 30 mmol/L glucose for 48 h was adopted.

277 Chronic HG culture moderately increased thrombin activity in HUVECs compared with normal
278 glucose group (Fig. 4A), while dramatically ($P < 0.05$) up-regulated PAR-1 protein expression
279 (Fig. 4B). The results were similar to those in GDM patients (Fig. 1A, B). Nonetheless, both
280 PAR-1 antagonism with vorapaxar and thrombin inhibition with argatroban reversed the increase
281 in PAR-1 protein expression in HG-cultured HUVECs (Fig. 4B), verifying a vital role of PAR-1
282 in vascular endothelial functions. Furthermore, treatment with a natural compound Sar
283 significantly ($P < 0.05$ or $P < 0.01$) declined thrombin activity and PAR-1 protein expression at
284 both 1.0 and 5.0 $\mu\text{mol/L}$ in HG-cultured HUVECs (Fig. 4A, B), demonstrating that Sar could
285 suppress thrombin/PAR-1 pathway.

286 3.4. Activation of AGEs/RAGE axis in HG-cultured HUVECs and effects of Sar

287 The formation of AGEs and protein expression of RAGE were also investigated in HG-cultured

288 HUVECs to seek for the potential mechanism of the activated thrombin/PAR-1 pathway.
289 Immunofluorescence study demonstrated that AGEs level was markedly increased in HG-cultured
290 HUVECs (Fig. 5A), and protein expression of RAGE was also remarkably ($P < 0.01$) up-regulated
291 in HUVECs exposed to chronic HG (Fig. 5B). However, both the AGEs levels and RAGE
292 expression were significantly ($P < 0.05$ or $P < 0.01$) decreased in all three concentrations of Sar
293 groups, compared to the untreated groups in HG-cultured HUVECs (Fig. 5A, B), suggesting a
294 strong inhibitory effect of Sar on AGEs/RAGE interaction.

295 3.5. Endothelial injury in HG-cultured HUVECs and effects of Sar

296 In order to examine whether the activated thrombin/PAR-1 pathway resulted in vascular
297 endothelial injury in prolonged HG condition, cell viability and LDH release were detected in
298 HG-cultured HUVECs. Figure 6A showed that cell viability was markedly ($P < 0.05$) decreased in
299 HUVECs cultured with HG for 48 h related to that in HUVECs cultured with normal glucose, and
300 LDH release was remarkably ($P < 0.01$) promoted in HG-cultured HUVECs (Fig. 6B).

301 Nonetheless, a PAR-1 antagonist or a thrombin inhibitor significantly ($P < 0.05$ or $P < 0.01$)
302 reduced LDH release in HG-cultured HUVECs, and the effect of PAR-1 antagonism was better
303 than that of thrombin inhibition (Fig. 6B). These reflected a contribution of the thrombin/PAR-1
304 pathway to vascular endothelial injury under the high glucose conditions. Moreover, cell viability
305 and LDH release were significantly ($P < 0.05$ or $P < 0.01$) ameliorated by Sar at the
306 concentrations of 0.2, 1.0, and 5.0 $\mu\text{mol/L}$ in HG-cultured HUVECs (Fig. 6A, B).

307 3.6. Activation of the NLRP1 inflammasome in HG-cultured HUVECs and effects of Sar

308 In order to explore whether the NLRP1 inflammasome was activated in HUVECs exposed to
309 chronic HG, protein expressions of NLRP1 and cleaved-caspase 1 as well as the levels of IL-18

310 and IL-1 β were determined. Results indicated that NLRP1 inflammasome was significantly
311 activated in HG-cultured HUVECs, as evidenced by the increased protein expressions of NLRP1
312 ($P < 0.01$) and cleaved-caspase 1 ($P < 0.05$), and the elevated levels of IL-18 and IL-1 β (both $P <$
313 0.01), compared with the culture with normal glucose (Fig. 7A-D). Moreover, treatment with Sar
314 at 1.0 or 5.0 $\mu\text{mol/L}$ had similar ameliorative effects to thrombin/PAR-1 pathway inhibition on the
315 activation of NLRP1 inflammasome in HG-cultured HUVECs, while 0.2 $\mu\text{mol/L}$ Sar mildly
316 improved these indices (Fig. 7A-D). Together with our previous report [27], we could conclude
317 Sar indeed had an inhibitory efficacy on NLRP1/3 inflammasome.

318 3.7. Interaction between AGEs/RAGE axis and thrombin/PAR-1 pathway in HG-cultured
319 HUVECs

320 To verify whether the activated thrombin/PAR-1 pathway was associated with the enhanced
321 AGEs/RAGE interaction in HG-cultured HUVECs, both thrombin activity and PAR-1 expression
322 were assessed in the presence and absence of AGEs inhibition or RAGE antagonism. It was found
323 that protein expression of PAR-1 was markedly (both $P < 0.01$) reduced in HUVECs co-cultured
324 with HG plus either aminoguanidine (AG, a typical inhibitor of AGEs formation) or FPS-ZM1 (a
325 high-affinity antagonist of RAGE) (Fig. 8A), as well as co-culture with HG and high
326 concentration of Sar (Fig. 8A). However, thrombin activity was not changed in HUVECs
327 co-cultured with HG plus either aminoguanidine or FPS-ZM1, compared with HG culture alone
328 (Fig. 8B), but thrombin activity was still significantly ($P < 0.05$) decreased after co-culture with
329 HG and high concentration of Sar (Fig. 8B). These results demonstrated that it was thrombin
330 receptor PAR-1 not thrombin itself that was influenced by AGEs/RAGE axis in HUVECs in HG
331 condition. On the other hand, high glucose co-culture with a thrombin inhibitor argatroban or a

332 PAR-1 antagonist vorapaxar markedly attenuated the increase in AGEs level in HUVECs (Fig.
333 5A), and greatly ($P < 0.05$ or $P < 0.01$) suppressed the expression of RAGE (Fig. 5B), compared
334 with HG culture alone. Taken together, a crosstalk may exist between thrombin/PAR-1 pathway
335 and AGEs/RAGE axis in vascular endothelial injury in high glucose condition.

336 3.8 Thrombin/PAR-1 pathway mediated the activation of NLRP1 inflammasome in HG-cultured
337 HUVECs

338 The mechanism of the proinflammatory effect of activated thrombin/PAR-1 pathway was
339 explored from the point of NLRP1 inflammasome activation in HG-cultured HUVECs. Compared
340 with high glucose culture alone, high glucose co-culture with a thrombin inhibitor argatroban or a
341 PAR-1 antagonist vorapaxar reversed the increases in NLRP1, cleaved-caspase 1, IL-18, and
342 IL-1 β levels in HG-cultured HUVECs (Fig. 7A-D), showing that activated thrombin/PAR-1
343 pathway may cause NLRP1 inflammasome activation in HG-cultured HUVECs. To further testify
344 this relationship, a HUVEC line with a stable PAR-1 knockdown by using short hairpin RNA
345 (shRNA) was established. The interference efficiency of F2R shRNA (F2R as the gene symbol of
346 PAR-1) (Fig. 9) was enough to perform the following experiment. It was found that NLRP1 and
347 IL-18 levels were dramatically (both $P < 0.01$) decreased in HG-cultured HUVECs with PAR-1
348 knockdown, compared to those in HG-cultured HUVECs with normal PAR-1 expression (Fig.
349 10A, B). The similar results were obtained by using HG co-treatment with high concentration of
350 Sar (i.e. HG+Sar-5) in the condition of PAR-1 knockdown (Fig. 10A, B). Altogether, we could
351 obtain that the proinflammatory effect of activated thrombin/PAR-1 pathway was achieved
352 through the activation of NLRP1 inflammasome in vascular endothelium in high glucose
353 condition.

354 4. Discussion

355 In this study, we found that thrombin/PAR-1 pathway, the NLRP1 inflammasome, and
356 AGEs/RAGE axis were activated in the umbilical cord of GDM patients. In HUVECs cultured
357 with chronic high glucose, the above mentioned pathways were also activated, in couple with
358 noteworthy endothelial injuries. Further studies demonstrated that there may be a crosstalk
359 between AGEs/RAGE axis and thrombin/PAR-1 pathway, followed by the activation of NLRP1
360 inflammasome in HG-cultured HUVECs. Moreover, a natural compound sarsasapogenin
361 ameliorated endothelial damages caused by chronic high glucose, which was achieved through
362 suppressing vascular inflammation mediated by both AGEs/RAGE axis and thrombin/PAR-1
363 pathway.

364 The physiological changes of blood coagulation occur in normal pregnancy and might be at a
365 prethrombotic state, evidenced by both the increased coagulation activity and the reduced
366 anticoagulation and fibrinolytic activity [4]. Gumus et al. reported that thrombin-activatable
367 fibrinolysis inhibitor antigen levels in plasma were significantly higher in pregnant women with
368 GDM when compared with controls, and may contribute to the decreased fibrinolytic potency,
369 causing a thrombophilic state [7]. The present study indicated that thrombin activity was markedly
370 elevated in the umbilical cord of GDM patients and HG-cultured HUVECs. Furthermore, protein
371 expression of PAR-1 was significantly raised in both the umbilical cord of GDM patients and
372 HG-cultured HUVECs, indicating that thrombin/PAR-1 pathway was activated in the vascular
373 endothelial cells in GDM condition.

374 Obvious vascular endothelial injury happens in GDM condition, which is closely related to
375 inflammation [11]. Accumulating data suggest that inflammasomes, mainly NLRP3 and NLRP1,

376 are involved in the generation of tissue or organ damage through exaggerating systemic and
377 organ-specific inflammatory responses [33]. We found that the NLRP1 inflammasome was
378 activated in GDM patients, for protein expressions of its main components NLRP1 and
379 cleaved-caspase 1 in the umbilical cord and its product IL-18 levels in plasma were remarkably
380 elevated. Similarly, the NLRP1 inflammasome was also activated in HG-cultured HUVECs,
381 accompanied by the damaged endothelial functions. Additionally, Jiang et al. reported that the
382 NLRP3 inflammasome activation was also involved in HG-induced endothelial injury in HUVECs
383 [20]. On the other hand, thrombin is a potent modulator of endothelial function, and
384 thrombin-dependent adhesion of monocytes to endothelial cells requires an intact endothelial
385 CARMA3·Bcl10·MALT1 signalosome [17], and up-regulation of PAR-1 is critically involved in
386 the co-activation of coagulation and inflammatory responses caused by thrombin [14]. In the
387 present study, co-treatment with high glucose and a thrombin inhibitor argatroban or a PAR-1
388 antagonist vorapaxar reversed the increases in NLRP1, cleaved-caspase 1, IL-18, and IL-1 β levels
389 in HG-cultured HUVECs. Moreover, NLRP1 and IL-18 were markedly decreased in HUVECs
390 cultured with HG after PAR-1 knockdown by using F2R shRNA. These results demonstrated that
391 the activated NLRP1 inflammasome was due to activation of the thrombin/PAR-1 pathway in
392 endothelial cells in GDM condition.

393 AGEs may prime pro-inflammatory mechanisms through RAGE in endothelial cells, thereby
394 amplifying pro-inflammatory mechanisms in chronic inflammatory disorders [34]. RAGE
395 expression was significantly increased in the omental adipose tissue explant from GDM subjects,
396 and its ligand high mobility group box 1 protein was markedly elevated in fetal membranes from
397 GDM subjects [35]. Our finding showed that AGEs levels and RAGE protein expression were

398 remarkably raised in the umbilical cord of GDM patients. Coincidentally, Tang et al. found that
399 AGEs/RAGE axis was activated in the rat model of GDM, and secretory RAGE showed a
400 protective effect on fetal development [36]. Furthermore, our cell experiments demonstrated that
401 AGEs/RAGE axis was similarly activated in HG-cultured HUVECs, and Rajaraman et al. reported
402 that HG caused vascular inflammation through AGEs mediated multiple axes besides
403 AGEs/RAGE axis in the primary culture of HUVECs [37]. These studies reinforce the enhanced
404 AGEs/RAGE interaction in vascular endothelium in chronic high glucose exposure.

405 Importantly, our observations showed that AGEs inhibition or RAGE antagonism markedly
406 decreased PAR-1 protein expression (Fig. 8A) in HG-cultured HUVECs, but did not affect
407 thrombin activity (Fig. 8B), exhibiting that the enhanced AGE/RAGE interaction mediated
408 HG-induced PAR-1 up-regulation in HUVECs. On the other hand, thrombin inhibition or PAR-1
409 antagonism significantly declined not only AGEs levels (Fig. 5A) but also RAGE protein
410 expression in HG-cultured HUVECs (Fig. 5B). Additionally, Ishibashi et al. reported that AGEs
411 potentiated the citrated plasma-induced oxidative and inflammatory reactions in endothelial cells
412 via the activation of thrombin/PAR-1 system, and blockade of the crosstalk between AGEs/RAGE
413 axis and coagulation system might be a novel therapeutic target for thromboembolic disorders in
414 diabetes [16]. In short, these results revealed an interaction between AGE/RAGE axis and
415 thrombin/PAR-1 pathway in endothelial injuries in prolonged high glucose condition.

416 The present study also testified that a natural compound Sar had an ameliorative effect on
417 endothelial damages against chronic high glucose. Timosaponin BII and AIII, the natural
418 glycosides of Sar, possess strong antiplatelet and antithrombotic effects [21, 22]. Our study
419 indicated that Sar could inhibit the activation of thrombin/PAR-1 pathway in HG-cultured

420 HUVECs, which may be the reasons for the antiplatelet and antithrombotic effects of the
421 glycosides of Sar. Moreover, timosaponin BII, AIII, and Sar show powerful anti-inflammatory
422 actions mainly through inhibiting NF-kappaB signal pathway and MAPK pathway [23-26]. In the
423 current study, we found that Sar remarkably suppressed the activated NLRP1 inflammasome in
424 HG-cultured HUVECs, which further clarified the action mechanism of anti-inflammatory
425 efficacy of Sar and its glycosides. Meanwhile, our results indicated that Sar significantly inhibited
426 AGEs/RAGE interaction in HG-cultured HUVECs. In addition, our previous report demonstrated
427 that Sar restrained the activation of AGEs/RAGE axis in the kidney of rats with diabetic
428 nephropathy [27]. Therefore, these findings indicated that Sar showed good protection against
429 chronic high glucose-induced endothelial damages through several pathways, suggesting Sar a
430 multi-target compound.

431 In summary, our findings demonstrated that high glucose-induced endothelial damage in GDM
432 was associated with thrombin/PAR-1 pathway mediated activation of the NLRP1 inflammasome,
433 and there may be an interaction between thrombin/PAR-1 pathway and AGEs/RAGE axis in
434 endothelial damages in high glucose state (Fig. 11). Moreover, Sar could act as a multi-target
435 protective agent against endothelial injury in prolonged HG condition (Fig. 11).

573

574 **Fig. 4** Effects of sarsapogenin (Sar) on thrombin activity (A) and PAR-1 expression (B) in
575 HUVECs cultured with high glucose for 48 h. NG, HG, HG+Sar-0.2, HG+Sar-1, HG+Sar-5,
576 HG+Vor, and HG+Arg groups: cells treated with 5.6 mmol/L glucose, 30 mmol/L glucose, 30
577 mmol/L glucose plus 0.2, 1, 5 $\mu\text{mol/L}$ Sar, 1.0 $\mu\text{mol/L}$ vorapaxar (Vor, a selective PAR-1
578 antagonist), or 1.0 $\mu\text{mol/L}$ argatroban (Arg, a typical inhibitor of thrombin), respectively. The 50
579 μg protein was loaded onto the gel in Western blot detection. Mean \pm SEM, thrombin (n=6),
580 PAR-1 (n=3). * $P<0.05$, compared with NG; # $P<0.05$, ## $P<0.01$, compared with HG.

581

582 **Fig. 5** Effects of sarsasapogenin (Sar) on AGEs levels (A) and protein expression of RAGE (B) in
583 HUVECs treated with high glucose for 48 h. NG, HG, HG+Sar-0.2, HG+Sar-1, HG+Sar-5,
584 HG+Vor, and HG+Arg groups: cells treated with 5.6 mmol/L glucose, 30 mmol/L glucose, 30
585 mmol/L glucose plus 0.2, 1, 5 $\mu\text{mol/L}$ Sar, 1.0 $\mu\text{mol/L}$ vorapaxar (Vor, a selective PAR-1
586 antagonist), or 1.0 $\mu\text{mol/L}$ argatroban (Arg, a typical inhibitor of thrombin), respectively. The 50
587 μg protein was loaded onto the gel in Western blot detection. Mean \pm SEM, RAGE (n=3). ** $P <$
588 0.01, compared with NG; # $P < 0.05$, ## $P < 0.01$, compared with HG.

589

590 **Fig. 6** Effects of sarsasapogenin (Sar) on cell viability (A) and LDH release (B) in HUVECs
591 cultured with high glucose for 48 h. NG, HG, HG+Sar-0.2, HG+Sar-1, HG+Sar-5, HG+Vor, and
592 HG+Arg groups: cells treated with 5.6 mmol/L glucose, 30 mmol/L glucose, 30 mmol/L glucose
593 plus 0.2, 1, 5 $\mu\text{mol/L}$ Sar, 1.0 $\mu\text{mol/L}$ vorapaxar (Vor, a selective PAR-1 antagonist), or 1.0
594 $\mu\text{mol/L}$ argatroban (Arg, a typical inhibitor of thrombin), respectively. Mean \pm SEM, n=3.
595 * $P < 0.05$, ** $P < 0.01$, compared with NG; # $P < 0.05$, ## $P < 0.01$, compared with HG.

596

597 **Fig. 7** Effects of sarsasapogenin (Sar) on protein expressions of NLRP1 (A), cleaved caspase-1
598 (B), IL-18 (C), and IL-1 β (D) in HUVECs treated with high glucose for 48 h. NG, HG,
599 HG+Sar-0.2, HG+Sar-1, HG+Sar-5, HG+Vor, and HG+Arg groups: cells treated with 5.6 mmol/L
600 glucose, 30 mmol/L glucose, 30 mmol/L glucose plus 0.2, 1, 5 $\mu\text{mol/L}$ Sar, 1.0 $\mu\text{mol/L}$ vorapaxar
601 (Vor, a selective PAR-1 antagonist), or 1.0 $\mu\text{mol/L}$ argatroban (Arg, a typical inhibitor of
602 thrombin), respectively. The 50 μg protein was loaded onto the gel in Western blot detection.

603 Mean \pm SEM, NLRP1 (n=5), cleaved caspase-1 (n=4), IL-18 and IL 1 β (n=3). * P < 0.05, ** P <
604 0.01, compared with NG; # P <0.05, ## P <0.01, compared with HG.

605

606 **Fig. 8** Effects of inhibition of AGEs/RAGE axis on PAR-1 expression (A) and thrombin activity
607 (B) in HUVECs cultured with high glucose for 48 h. HG, HG+Sar-5, HG+AG, and HG+FPS-ZM1
608 groups represent cells treated with 30 mmol/L glucose, 30 mmol/L glucose plus 5 μ mol/L Sar, 1
609 μ mol/L aminoguanidine (AG, a typical inhibitor of AGEs formation), or 1 μ mol/L FPS-ZM1 (a
610 high-affinity inhibitor of RAGE), respectively. The 50 μ g protein was loaded onto the gel in
611 Western blot detection. Mean \pm SEM, PAR-1 (n=5), thrombin (n=6). * P <0.05, ** P <0.01,
612 compared with HG.

613

614 **Fig. 9** Interference efficiency of F2R shRNA (shF2R) was performed in HUVECs. (A) HUVECs
615 infected with lentivirus containing F2R shRNA (F2R as the gene symbol of PAR-1) under
616 bright-field microscopy illumination, and fluorescent light in the same field showed stable and
617 high expression of green fluorescent protein (GFP). (B) The protein levels of PAR-1 by Western
618 blot using 50 μ g total proteins. Mean \pm SEM, n=3, ** P <0.01, compared with vehicle (shNC).

619

620 **Fig. 10** Effects of PAR-1 knockdown on protein expressions of NLRP1 (A) and IL-18 (B) in
621 HUVECs treated with high glucose for 48 h. HG, HG+Sar-5, shF2R+HG, and shF2R+HG+Sar-5
622 groups represent cells infected with lentivirus containing F2R negative control (shNC) or F2R
623 shRNA (F2R, the gene symbol of PAR-1) subsequently cultured with HG or HG plus 5 μ mol/L
624 Sar, respectively. The 50 μ g protein was loaded onto the gel in Western blot detection. Mean \pm

625 SEM, NLRP1 (n=3), IL-18 (n=5). $**P < 0.01$, compared with HG; $\#P < 0.05$, $\#\#P < 0.01$, compared
 626 with HG+Sar-5.
