Abstract

Background: Angiotensin-converting enzyme 2 (ACE2) converts angiotensin II (Ang II), a potent vasoconstrictor, to Ang 1-7 and is also a membrane protein that enables COVID-19 infectivity. AMP-activated protein kinase (AMPK) phosphorylation of ACE2 enhances ACE2 stability. This mode of post-translational modification (PTM) of ACE2 in vascular endothelial cells (ECs) is causative of a pulmonary hypertension (PH)-protective phenotype. The oncoprotein murine double minute 2 (MDM2) is an E3 ligase that ubiquitinates its substrates to cause their degradation. In this study, we investigated whether MDM2 is involved in the PTM of ACE2 via its ubiquitination of ACE2, and whether an AMPK and MDM2 crosstalk regulates the pathogenesis of PH.

Methods: Bioinformatic analyses were used to explore E3 ligase that ubiquitinates ACE2. Cultured endothelial cells, mouse models, and specimens from patients with idiopathic pulmonary arterial hypertension were used to investigate the crosstalk between AMPK and MDM2 in regulating ACE2 phosphorylation and ubiquitination in the context of PH.

Results: Levels of MDM2 were increased and those of ACE2 decreased in lung tissues or pulmonary arterial endothelial cells from patients with idiopathic pulmonary arterial hypertension and rodent models of experimental PH. MDM2 inhibition by JNJ-165 reversed the SU5416/hypoxia-induced PH in C57BL/6 mice. ACE2-S680L mice (dephosphorylation at S680) showed PH susceptibility, and ectopic expression of ACE2-S680L/K788R (deubiquitination at K788) reduced experimental PH. Moreover, ACE2-K788R overexpression in mice with endothelial cell-specific AMPK α 2 knockout mitigated PH.

Conclusions: Maladapted PTM (phosphorylation and ubiquitination) of ACE2 at Ser-680 and Lys-788 is involved in the pathogenesis of pulmonary arterial hypertension and experimental PH. Thus, a combined intervention of AMPK and MDM2 in the pulmonary endothelium might be therapeutically effective in PH treatment.

Key Words: ACE2; MDM2; Pulmonary arterial hypertension; pulmonary endothelium; pulmonary vascular remodeling

Non-standard Abbreviations and Acronyms

ACE	angiotensin-converting enzyme
Ang	angiotensin
CHX	cycloheximide
AMPK	AMP-activated protein kinase
ANGPT1	angiopoietin 1
BMPR2	bone morphogenetic protein receptor type 2
ECs	endothelial cells
EDN1	endothelin-1
iPSC	induced pluripotent stem cell
IL-1 β	interleukin 1 β
IL-6	interleukin 6
IPAH	idiopathic pulmonary arterial hypertension
MCP-1	monocyte chemoattractant protein-1
MCT	monocrotaline
MDM2	murine double minute 2

MIB1	mindbomb E3 ubiquitin protein ligase 1
mPAP	mean pulmonary arterial pressure
NEDD4L	neural precursor cell expressed developmentally downregulated gene 4-like
PAH	pulmonary arterial hypertension
PAEC	pulmonary artery endothelial cell
PASMC	pulmonary artery smooth muscle cell
PDGFA	platelet derived growth factor subunit A
PH	pulmonary hypertension
PTGIS	prostacyclin synthase
PTM	post-translational modifications
RAS	renin–angiotensin system
RVSP	right ventricular systolic pressure
SBP	systolic blood pressure
SuHx	SU5416/hypoxia
VCAM-1	vascular cell adhesion molecule 1
VEGF	vascular endothelial growth factor

Clinical Perspective

What is new?

- MDM2 expression is increased in lung tissues from patients with idiopathic PAH and animals with experimental PH.
- MDM2, an E3 ligase of ACE2, ubiquitinates ACE2 at K788. AMPK phosphorylates ACE2 at S680 and inhibits MDM2-mediated ubiquitination of ACE2 at K788.
- Functionally, ACE2 phosphorylation and deubiquitination increase the eNOS-mediated NO bioavailability in ECs.

What are the clinical implications?

- Inhibition of MDM2 (e.g., by JNJ-165) has great therapeutic potential for PAH/PH by stabilizing ACE2.
- Post-translational modification of ACE2 is a novel strategy to develop new therapies for PAH/PH.

Introduction

The renin–angiotensin system (RAS) regulates blood pressure, fluid and electrolyte balance, and vascular resistance.¹ Sustained pulmonary vasoconstriction, concentric pulmonary vascular remodeling and *in situ* thrombosis are major causes for the elevated pulmonary vascular resistance and pulmonary arterial pressure in patients with pulmonary arterial hypertension (PAH).^{2,3} Within the RAS system, the angiotensin-converting enzyme 2 (ACE2)/angiotensin (Ang)-(1-7)/Mas receptor axis counterposes the ACE1/Ang II/AT1 receptor axis. With a homologous catalytic domain as for ACE1, ACE2 competes with ACE1 to convert Ang II to Ang 1-7, which provides anti-vasoconstrictive, anti-inflammatory, anti-hypertrophic, and anti-fibrotic effects on various vascular beds including the pulmonary vasculature.^{4,5} Thus, inhibiting the canonical RAS (i.e., ACE1) and activating the counterbalancing ACE2/Ang 1-7/Mas axis have complementary efficacies in cardiovascular diseases, including pulmonary hypertension (PH).⁶⁻⁸

Post-translational modifications (PTMs) play an essential role in regulating protein expression, activity, and subcellular distribution. As two major modes of PTMs, protein phosphorylation and ubiquitination are critical for cellular responses to physiological and pathophysiological stimuli.^{9,10} We have previously shown that AMP-activated protein kinase (AMPK) phosphorylates ACE2 Ser-680 (S680) in vascular endothelial cells (ECs) and thereby inhibits the proteasome-mediated ubiquitination of ACE2.⁸ Consequently, ACE2 stability is increased under conditions in which AMPK is activated (e.g., metformin treatment).^{11,12} Activation of the AMPK-ACE2 axis is beneficial to the pulmonary endothelium, as supported by the pulmonary hypertension (PH)-resistant phenotype seen in a mouse line harboring the phospho-mimetic form of ACE2 (i.e., ACE2-S680D).⁸ However, the molecular basis underlying

ACE2 ubiquitination leading to its degradation and its correlation with the onset of PAH remains elusive.

Murine double minute 2 (MDM2), or HDM2 in humans, is an oncoprotein, in part via its negative regulation of p53.¹³⁻¹⁵ Functioning as an E3 ubiquitin ligase, MDM2 ubiquitinates p53 and induces p53 protein degradation.¹⁶⁻¹⁸ MDM2 is upregulated in diverse cancer cell types, including but not limited to, colorectal adenocarcinoma, breast carcinomas, lung cancer, and osteogenic sarcoma.^{13,19} JNJ-26854165 (JNJ-165), an oral MDM2 inhibitor, can induce apoptosis and decrease proliferation in various tumor models.^{20,21} Dysregulated MDM2 is also implicated in cardiovascular impairments. For example, MDM2 overexpression enhances vascular calcification by ubiquitinating histone deacetylase 1.²² Nutlin-3a, a small molecule antagonist of MDM2, mitigates both PH and retinal angiogenesis by decreasing the proliferation of pulmonary artery smooth muscle cells (PASMCs) and ECs, respectively.^{23,24}

In this study, we explored the role of MDM2 and its cross talk with AMPK in regulating the expression of ACE2 in the pulmonary endothelium. Our results showed that AMPK phosphorylation of ACE2 at S680 hindered MDM2 ubiquitination of ACE2 at K788 in ECs. In concert, these two PTM-associated mechanisms regulated the stability of ACE2. A maladapted PTM of ACE2 is implicated in the pulmonary endothelium in patients with idiopathic pulmonary arterial hypertension (IPAH) and several animal models of experimental PH.

Methods

The data that support the findings of this study are available from the corresponding author upon reasonable request.

Cell cultures and reagents

Human pulmonary artery ECs (PAECs) were obtained from Pulmonary Hypertension Breakthrough Initiative (PHBI). Demographic and clinical data of Controls and IPAH patients are in Supplemental Table I. Based on PHBI facility's protocol,²⁵ the cells were isolated from lung tissues of health controls and IPAH patients and cultured in endothelial cell growth medium (EGM-2; Lonza) on fibronectin-coated plates. Cells were passaged at 70-80% confluence by dissociation from plates using Trypsin-EDTA. Primary cultures of passage 5-8 were used in experiments. PAEC authentication was carried out using antibodies against the EC markers, CD31, vWF and VE-cadherin, and FACS/ICC. The percentage of positively stained with these EC-markers was over 93%. HUVECs were cultured in M199 medium (Sigma-Aldrich). HEK293 cells and BAECs were obtained from ATCC and maintained in DMEM (Life Technologies). All cell cultures were maintained at 37°C in 95% air and 5% CO₂.

The reagents used and their commercial sources were as follows: SU5416 (Cayman); cycloheximide (CHX), MG132, and monocrotaline (MCT) (Sigma-Aldrich); JNJ26854165 (Selleckchem); Ang 1-7 ELISA kit (Peninsula Laboratories International); Microfil MV-122, MV-Diluent, and MV curing agent (Flow Tech); anti-ACE2 and anti-ACE1 (Abcam); anti-Ub, anti-eNOS, and anti- α -tubulin (Cell Signaling Technology); anti-MDM2, anti- β -actin and anti-GAPDH (Santa Cruz Biotechnology); anti-peNOS (S1177), anti-peNOS (T495), and (BD Biosciences). Expression plasmids encoding ACE2, ubiquitin, eNOS, MDM2, and MDM2 C464A were purchased from Addgene. ACE2 Ser-680 was mutated to Asp (D) or Leu (L) and Lys-788 to Arg (R) by using the QuikChange Lightning Multi Site-Directed Mutagenesis Kit (Agilent Technologies).

Human lung samples

Human lung specimens were from normal donor lungs or explanted lungs from subjects with IPAH undergoing lung transplantation at UCSD. The study was approved by the UCSD IRB, written informed consent was obtained from all participants. Demographic and clinical data of Controls and IPAH patients are in Supplemental Table I.

Cell transfection and virus infection

MDM2 siRNA or scramble control RNA (Qiagen) 20 nM was transfected into various cell types at a concentration of with the use of Lipofectamine RNAi Max (Invitrogen). Adenoviruses overexpressing ACE2 wild-type (WT), S680D, S680L, or S680L/K788R were created by using the ViraPower Adenoviral Expression System (Invitrogen), with protocols provided by the manufacturer. Adenovirus-driven ectopic expressing ACE2 (WT) and the various ACE2 mutants in cells were achieved by infecting cultured cells at 10 MOI.

In silico method

UbiBrowser (<http://ubibrowser.ncpsb.org>) was used to predict the E3 ligases. Combining confidence and evidence modes, a list of putative MDM2 E3 ligases is shown in Supplemental Table II. For the heatmap shown in Figure 1C, we analyzed a GEO RNA-seq dataset (GSE79613) generated from the induced pluripotent stem cell (iPSC)-derived ECs from patients with PAH²⁶ with the online tool GENE_E (Morpheus) used to produce the presented heatmap.

Western blot analysis, immunoprecipitation, and qRT-PCR

Cells or tissue was lysed in the EBC buffer supplemented with protease inhibitors (Thermo Scientific), phosphatase inhibitors (Roche), and ubiquitinase inhibitors (Sigma-Aldrich). Lysates were resolved by SDS-PAGE and immunoblotted with antibodies as indicated. For immunoprecipitation, the lysates were incubated with the described antibodies for 4 hr at 4°C,

followed by 2-hr incubation with Dynabeads Protein G (Life Technologies). Immunoprecipitated products were washed with the NETN buffer before resolved by SDS-PAGE and immunoblotting with the indicated antibodies. For quantitative real-time PCR (qRT-PCR): RNA was extracted from homogenized tissue or cells by using TRIzol reagent (Invitrogen). The cDNA was synthesized by using Takara (Clontech Laboratories). qPCR was performed using SYBR Green Realtime PCR Master Mix (Bio-Rad) with GAPDH or β -actin as internal controls. The relative gene expression was quantified by the $\Delta\Delta C_q$ method. Primer sequences used for qPCR are listed in Supplemental Table III.

Animal studies, hemodynamics, histology, and pulmonary angiogram

Animal experiments were approved by Institutional Animal Care and Use Committee (IACUC) of University of California, San Diego and the Institutional Animal Ethics Committee of Xi'an Jiaotong University. Adult male mice at 8 weeks old were given SU5416 (20 mg/kg) once a week and placed under 10% hypoxia for 5 weeks (12-hr light/dark cycle). JNJ-165 was administered daily via oral gavage for the last 2 weeks, and adenovirus (Ad-null, Ad-ACE2L K788R, Ad-ACE2-WT and ACE2-K788R) (5×10^8 PFUs) were delivered intratracheally (once). Right ventricular systolic pressure (RVSP) and systemic systolic blood pressure (SBP) were measured with standardized protocols. Fulton index (right ventricular hypertrophy) was determined as the ratio of the right ventricular weight to those of the left ventricle + septum weight. For investigating vessel wall remodeling, formaldehyde-fixed, paraffin-embedded lung tissue sections were stained with hematoxylin and eosin staining and observed under a NanoZoomer Slide Scanner. For pulmonary angiography, Mice were anesthetized by pentobarbital sodium (120 mg/kg) via intraperitoneal injection. The chest was opened by median sternotomy and thymus and adipose tissue were carefully excised. Heparin (20 IU) was

immediately injected into the right ventricle to prevent blood from coagulation. A catheter composed of PE-20 tubing was inserted into the main pulmonary artery (PA) via the right ventricle, which was ligated together with ascending aorta using a 6-0 black silk suture. Mouse lung was initially perfused with PBS 0.05mL/min for 3 minutes using PE-20 tubing until lung turns white and then was perfused with Microfil, a casting agent at 0.05mL/min. Microfil composition consists of 600 μ L of Microfil and 750 μ L of diluent. Just before microfil perfusion, 67.5 μ L of curing agent was added. The working time of the Microfil solution is 15 minutes. Lungs were left overnight at 4°C covered with wet paper in order to avoid drying of lungs. Following day, the lungs were separated carefully and placed in PBS and kept gently shaking for 15 mins at RT. PBS were removed and lungs underwent gradient dehydration using ethyl alcohol (50%, 70%, 80%, 95%, and 100% twice) per hour to digest lung tissue. After dehydration, lungs were immersed in Methyl salicylate to view the lung vasculature. Lungs were photographed with a camera (MU1000, FMA050, Amscope, CA). The periphery of lung was selected with Photoshop and converted to binary images using NIH Image J to quantitate the total branch length, number of branches and number of junctions normalized to area used for analysis.

Statistics

All statistical analyses were performed with SPSS 14.0 or GraphPad Prism 7 software. The numbers in figure legends indicate biological replicates performed in each experiment. Initially, the data sets were analyzed for normality using the Shapiro-Wilk test ($P < 0.05$) and equal variance using the F test ($P > 0.05$). For data with normal distribution, two-tailed Student *t*-test was used to compare two groups and one-way ANOVA with Bonferroni post-hoc test for multiple groups. Two-way ANOVA was used in Figure 2D, 2E and 3D for comparison with two independent variables. For non-normally distributed data or experiments with small sample size

($n < 5$), Mann-Whitney U test was used to compare two groups and Kruskal-Wallis test for multiple groups. Data are expressed as mean \pm SEM and $p < 0.05$ was considered statistically significant.

Results

MDM2 is correlated with ACE2 in PH

We used UbiBrowser (<http://ubibrowser.ncpsb.org>) to explore the putative E3 ligases that can ubiquitinate ACE2.²⁷ Combined results of the confidence mode (Figure 1A) and evidence mode (Figure 1B) suggested that MDM2, neural precursor cell expressed developmentally downregulated gene 4-like (NEDD4L), and mindbomb E3 ubiquitin protein ligase 1 (MIB1) had the highest scores as E3 ligases to ubiquitinate ACE2. We then mined a GEO RNA-seq dataset (GSE79613; <https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE79613>) generated from the induced pluripotent stem cell iPSC-derived ECs from patients with familial PAH. The mRNA level of MDM2, but not that of NEDD4L, MIB1, and other E3 ligases was elevated in EC-derived iPSCs from familial PAH patients (heat map in Figure 1C). We validated these *in silico* results by examining the MDM2 and ACE2 expression levels in lung tissues from IPAH patients. The protein and mRNA levels of MDM2 were both increased but the protein level of ACE2 was decreased in lung tissues from IPAH patients versus healthy controls (Figure 1D and 1E), which was verified in PAECs from IPAH patients (Figure 1F and 1G) and lung tissues from mice with SU5416/hypoxia (SuHx)-induced PH (Figure 1H and 1I) and rats with MCT-induced PH (Figure 1J and 1K).

MDM2 is an E3 ligase of ACE2

In light of augmented MDM2 level and decreased ACE2 level in PAECs from patients with IPAH and lung tissues from rodents with experimental PH, we next explored whether MDM2 regulates ACE2 stability via its ubiquitination of ACE2 and hence affects the expression level of ACE2. MDM2 knockdown by siRNA or inhibition by JNJ-165, an agent targeting the MDM2 ubiquitinase catalytic domain (RING domain), increased ACE2 expression in PAECs (Figure 2A and 2B). By contrast, MDM2 overexpression in ECs decreased ACE2 level (Figure 2C). We performed a CHX pulse-chase experiment to determine whether MDM2 affected ACE2 stability. MDM2 knockdown prolonged but MDM2 overexpression shortened ACE2 half-life in HEK293 cells (Figure 2D and 2E). However, overexpression of the loss-of-function mutant MDM2 C464A (C464 in the RING domain is mutated to A)¹⁷ did not affect the protein half-life of ACE2. We next investigated whether MDM2 ubiquitinates ACE2 and therefore affects ACE2 stability. ACE2 ubiquitination was significantly attenuated in HEK293 cells treated with JNJ-165 or transfected with MDM2 siRNA (Figure 2Fa and Fb). Hypoxia induced ACE2 ubiquitination in HEK293 cells, which was significantly attenuated by MDM2 knockdown (Figure 2Fc). We also explored the interaction between MDM2 and ACE2. As shown in Figure 2G, exogenously expressed MDM2 and ACE2 in HEK 293 cells were reciprocally immuno-precipitated. The interaction between MDM2 and ACE2 was further confirmed by the endogenously expressed MDM2 and ACE2 in ECs (Figure 2H). Together, these results suggest that MDM2 ubiquitinated ACE2 leading to ACE2 degradation.

MDM2 ubiquitination of ACE2 at K788

By using UbPred (<http://www.ubpred.org>), we predicted that ACE2-K788 is a putative ubiquitination site (Figure 3A). K788 is located 108 a.a downstream of S680 which is

phosphorylated by AMPK.⁸ Given that AMPK increases ACE2 stability, we hypothesized that AMPK phosphorylation of S680 inhibits MDM2 ubiquitination of ACE2-K788. To test this hypothesis, we created ACE2-S680L, a dephospho-mimetic of ACE2 (ubiquitination-prone mutant), and ACE2-S680L/K788R, its ubiquitination-resistant counterpart. To examine the crosstalk between AMPK and MDM2 in regulating ACE2 expression level, we transfected HEK293 cells with ACE2-S680D (phospho-mimetic), ACE2-S680L, or ACE2-S680L/K788R. Level of ubiquitination was higher for ACE2-S680L than ACE2-S680D. However, ACE2-S680L/K788R reversed the ubiquitination of ACE2 (Figure 3B). Under hypoxia, level of ubiquitination was lower for ACE2-S680L/K788R than ACE2-S680L (Figure 3C). Additionally, CHX pulse-chase experiments showed remitted stability of ACE2-S680L/K788R (Figure 3D). Functionally, ACE2-S680L/K788R increased the eNOS-mediated NO bioavailability (i.e., increased S1177 phosphorylation and decreased T495 dephosphorylation) to a level similar to that of ACE2-S680D in both HEK293 cells and PAECs. In contrast, ACE1 expression level was lower in S680L/K788R-transfected cells than ACE2-S680L cells (Figure 3E and 3F). As the major proteolytic product of ACE2, Ang1-7 level was elevated by approximately 3 folds in PAECs overexpressing ACE2-S680D or ACE2-S680L/K788R as compared with ACE2-S680L (Figure 3G).

MDM2 inhibition mitigates PH in mice

We used three mouse models to infer the involvement of the AMPK/MDM2/ACE2 axis in PH. First, we compared the SuHx-induced PH in C57BL/6 mice administered with JNJ-165 or vehicle (Figure 4A). RVSP and Fulton index (RV/LV+septum [S] weight) were elevated in mice with 5-week SuHx treatment (Figure 4B and 4C). JNJ-165 administration at the beginning of 4th week ameliorated the SuHx-increased RVSP and RV hypertrophy (Figure 4B and 4C).

Consistent with changes in hemodynamics, mice receiving JNJ-165 showed abrogated pulmonary artery remodeling, as shown by the H&E staining (Figure 4D). Moreover, angiogram revealed better-preserved lung vasculature in mice receiving JNJ-165 (Figure 4E). At the molecular level, lung tissues from mice administered JNJ-165 showed lower levels of ACE2 ubiquitination and eNOS T494 phosphorylation as well as higher levels of eNOS S1176 phosphorylation and ACE2 (Figure 4F). Furthermore, we compared the mRNA levels of genes implicated in the development of PH, including endothelin-1 (EDN1), angiotensin 1 (ANGPT1), prostacyclin synthase (PTGIS) and bone morphogenetic protein receptor type 2 (BMPR2), in mouse lung tissues. JNJ-165 decreased the mRNA levels of EDN1 and ANGPT1 by approximately 0.3- and 0.5-fold, respectively but increased those of PTGIS and BMPR2 by approximately 2- and 3-fold, respectively in lung tissues from SuHx-PH mice (Figure 4G). On the other hand, JNJ-165 decreased the expression of genes involved in EC proliferation and inflammation, namely, vascular cell adhesion molecule 1 (VCAM-1), vascular endothelial growth factor (VEGF), platelet derived growth factor subunit A (PDGFA), interleukin 6 (IL-6), monocyte chemoattractant protein-1 (MCP-1), and interleukin 1 β (IL-1 β) in lung tissues in SuHx-PH mice (Figure 4H). We have also performed an additional set of experiments in which JNJ-165 was administered to C57BL/6 mice at the beginning of the 5-week period. As shown in Figure I in the Data Supplement, PH was significantly prevented in mice receiving JNJ-165 along with SuHx treatment. Collectively, Figure 4 and Figure I in the Data Supplement suggest the effect of MDM2 inhibition in reducing experimental PH, which was at least in part mediated through the rectified ACE2 expression.

ACE2-S680L/K788R attenuates PH in ACE2-S680L mice

Previously, we found that ACE2-S680D (mimicking constitutively phosphorylated ACE2-S680 leading to increased ACE2 expression) mice showed reduced PH.⁸ To substantiate the crosstalk between AMPK and MDM2 in regulating ACE2 in terms of PAH, we created an ACE2-S680L (mimicking constitutively dephosphorylated ACE2-S680 leading to decreased ACE2 expression) mouse line. As compared with their ACE2-S680D counterparts, SuHx treatment caused aggravated PH in ACE2-S680L mice, as demonstrated by elevated RVSP, increased Fulton index, and vascular remodeling (Figure 5A through 5D). The enhanced PH in ACE2-S680L mice was reminiscent of EC-AMPK α 2^{-/-} and ACE2^{-/-} mice.⁸ To test whether inhibition of ACE2-K788 ubiquitination attenuates PH, we administered ACE2-S680L mice an adenovirus expressing ACE2-S680L/K788R (Ad-ACE2-S680L/K788R) via intratracheal injection. Overexpression of the exogenous ACE2-S680L/K788R (mimicking constitutively dephosphorylated ACE2-S680 and deubiquitinated K788 leading to increased ACE2 expression) mitigated PH in ACE2-S680L mice (Figure 5B through 5D). However, systolic blood pressure was not significantly different between these groups (Figure II in the Data Supplement). As expected, ACE2 level was lower in the lung of ACE2-S680L than ACE2-S680D mice under SuHx treatment, which was consistent with decreased NO bioavailability (Figure 5E). Regarding PH-related genes, mice overexpressing ACE2-S680L/K788R showed reduced mRNA levels of EDN1 (~ 0.3-fold) and ANGPT1 (~ 0.3-fold) and increased mRNA levels of PTGIS (~ 5-fold) and BMPR2 (~ 3-fold) (Figure 5F). Collectively, results in Figure 5 suggest that dephosphorylation of ACE2-S680 aggravates, but deubiquitination of ACE2-K788 mitigates, experimental PH.

ACE2-K788R improves PH in EC-AMPK α 2^{-/-} mice

To further decipher the role of MDM2 in modulating ACE2 via interacting with AMPK, we investigated whether ectopic expression of ACE2-K788R is sufficient to rescue SuHx-mediated PH in EC-AMPK α 2^{-/-} mice.⁸ To this end, EC-AMPK α 2^{-/-} mice were under SuHx for 3 weeks before adenovirus-null (Ad-null) and adenovirus-expressing wildtype ACE2 (Ad-ACE2-WT) or ACE2-K788R (Ad-ACE2-K788R) was introduced intratracheally. Two weeks later, we examined the effects of Ad-null, Ad-ACE2-WT or Ad-ACE2-K788R on SuHx-induced PH in EC-AMPK α 2^{-/-} mice. SuHx treatment significantly increased RVSP, mean pulmonary arterial pressure (mPAP; estimated according to the equation: mean PAP = 0.61RVSP+2 mmHg)²⁸ and RV contractility (RV- \pm dP/dt) in EC-AMPK α 2^{-/-} mice (Figure 6A). Overexpression of ACE2-K788R in pulmonary endothelium was confirmed by western blot revealing increased ACE2 level in lung ECs isolated from mice receiving Ad-ACE2-K788R (Figure III in the Data Supplement). Increased RVSP/mPAP was associated with significant pulmonary vascular remodeling as revealed by lung histology (Figure 6B), angiogram (Figure 6C), and RV hypertrophy (Figure 6D). Administration of Ad-ACE2-K788R significantly attenuated SuHx-induced PH. However, EC-AMPK α 2^{-/-} mice receiving Ad-ACE2-K788R exhibited less increases in RVSP/mPAP (Figure 6A), PA wall thickness (Figure 6B), Fulton Index (Figure 6D), and preserved PA branches (Figure 6C) than EC-AMPK α 2^{-/-} mice receiving Ad-null or Ad-ACE2-WT (Figure 6A through 6D). In line with the *in vivo* hemodynamic and *ex vivo* histological data, ACE2 ubiquitination was decreased and its expression was increased in SuHx-treated EC-AMPK α 2^{-/-} mice infected with Ad-ACE2-K788R compared to those infected with Ad-ACE2-WT (Figure 6E and 6F). Furthermore, eNOS S1176 phosphorylation was increased (~ 2.5-fold) and eNOS T494 phosphorylation was decreased by ~ 0.5-fold (Figure 6E); levels of EDN1 and

ANGPT1 mRNA were decreased by ~ 0.5- and 0.7-fold, respectively, and those of PTGIS and BMPR2 were increased by ~ 1.5- and 2-fold, respectively, in SuHx-treated EC-AMPK α 2^{-/-} mice with Ad-ACE2-K788R than Ad-null or Ad-ACE-WT (Figure 6F). Ad-ACE2-WT overexpression in EC-AMPK α 2^{-/-} mice did not significantly increase ACE2 level, whereas ACE2 ubiquitination level was much higher with SuHx, which indicates that omission of AMPK phosphorylation at S680 enhanced ACE2 ubiquitination. Together, these results suggest that AMPK phosphorylation at S680 was necessary for ACE2 deubiquitination at K788, which endowed a PH-resistant phenotype.

Discussion

In this study, we demonstrated that the expression level of ACE2 in ECs was co-regulated by a PTM mechanism involving AMPK and MDM2. The implication of this mechanism in PH builds on the observations that: (1) MDM2 level is increased and ACE2 level decreased in lung tissues and PAECs from patients with IPAH and in lung tissues from animals with experimental PH and (2) pharmacological inhibition of MDM2 (which increased ACE2) or genetic manipulation of ACE2 K788 (which rendered ACE2 more resistant to MDM2-mediated ubiquitination and degradation) attenuated the development of PH and partially reversed established PH in mice. Mechanistically, we demonstrated that an interplay between the AMPK-mediated phosphorylation of ACE2 at S680 and the MDM2-mediated ubiquitination of ACE2 at K788 played an important role in determining the level of ACE2. In mice with experimental PH, inhibition of ACE2 phosphorylation at S680 and upregulation of MDM2 expression resulted in ACE2 ubiquitination at K788 and consequently, ACE2 degradation (summarized in Figure 7).

The RAS is intricately balanced between the detrimental ACE1-Ang II-AT1R axis and the beneficial ACE2-Ang 1-7-Mas axis. Suppressed ACE2 and/or aggravated ACE1 have been implicated in PH.²⁹ Herein, the decreased level of ACE2 in lung tissues of animals with experimental PH and patients with IPAH, more specifically, in PAECs from these patients (Figure 1D through 1K) are in line with the previous reports. Although there might be various mechanisms involved in the regulation of the two axes, alone or in concert, the data from the current study indicated that MDM2 ubiquitination of ACE2 would decrease the ratio of ACE2 to ACE1. Consequently, impaired EC functions became evident, as suggested by the impaired eNOS-derived NO bioavailability (Figure 3F). Because ACE1 in the lung endothelium plays a critical role in regulating RAS in the cardiovascular system, the dysregulated MDM2-ACE2 might also potentiate the ACE1-Ang II-AT1R axis at the system level, which agrees with the increased serum level of Ang I and Ang II in patients with IPAH.³⁰

Sustained pulmonary vasoconstriction and excessive pulmonary vascular remodeling due to increased proliferation of PAECs, PSMCs, and fibroblasts are the major causes of the elevated pulmonary vascular resistance in patients with PAH.³¹ The ACE1-Ang II-AT1R arm promotes vasoconstriction, proliferation, and growth, which would be counteracted by the ACE2-Ang 1-7-Mas arm.³² We found that ACE2-S680 phosphorylation and ACE2 K788 deubiquitination increased eNOS-mediated NO production and Ang 1-7 in PAECs, which may account for the decreased RVSP seen in ACE2-S680D mice and S680L mice infected with ACE2-S680L/K788R adenovirus (Figure 5).

PAH has emerged as a cancer-like cardiovascular disease.^{33,34} This hypothetical notion is supported by the efficacy of anticancer drugs [e.g., imatinib (tyrosine kinase inhibitor), everolimus (mTOR inhibitor), and dichloroacetate (pyruvate dehydrogenase kinase inhibitor)] in

their use in clinical trials of PAH.³⁵ Related to the current work, given MDM2 inhibitors are being considered in preclinical experiments and clinical trials for solid malignancies, these drugs might be useful in treating PAH. One of these agents, JNJ-165 (also known as serdemetan) has been suggested to exert both p53-dependent and -independent effects on killing tumor cells.^{20,36} The therapeutic effect of MDM2 inhibitors on PAH, if any, would be attributable, at least in part, to their inhibition of the MDM2-ACE2 axis. Besides MDM2, other E3 ligases (e.g., NEDD4L and MIB1) are likely to be involved in ACE2 ubiquitination via their ubiquitination of K788 or other Lys residues. Thus, during the pathophysiological course of PAH, a number of E3 ligases in the pulmonary endothelium, including MDM2, are activated by the “cancer-like” milieu, which results in ACE2 ubiquitination leading to its degradation.

Data shown in Figures 5 and 6 suggest that ACE2-S680 phosphorylation is necessary and sufficient for K788 deubiquitination. In contrast, S680 dephosphorylation might potentiate K788 ubiquitination. Both S680 and K788 are located at the extracellular domain of ACE2 and PTM of these two residues might modify the 3-D conformation of ACE2, which either hider or favor the catalysis by MDM2. Of note, the binding of SARS-CoV-2 Spike glycoprotein (S-protein) to ACE2 is required for viral infection and development of COVID-19–associated lung diseases.³⁷⁻⁴⁰ Although knowledge is lacking whether COVID-19 aggravates PH, the current study leads us to speculate that COVID-19 is likely associated with EC dysfunction via dysregulated ACE2. Recombinant human ACE2 (rhACE2) can inhibit SARS-Cov-2 infection of engineered blood vessels.⁴¹ Because ACE2-S680D/K788R has a longer half-life than the wildtype ACE2, rhACE2-S680D/K788R might potentially be a better therapeutic strategy.

In summary, this study demonstrates a novel crosstalk between the metabolic regulator AMPK and oncoprotein MDM2 by which ACE2 in the lung vasculature is decreased to

contribute to the development of pulmonary arterial hypertension. Under normal or physiological conditions, AMPK-mediated ACE2 phosphorylation at S680 hinders MDM2-mediated ACE2 ubiquitination at K788 thus the ACE2 stability is maintained and ACE2-mediated conversion of Ang-II to Ang 1-7, as well as, eNOS-mediated NO production, is enhanced in lung ECs. A maladapted PTM modification of ACE2 results in the decrease of ACE2 stability due to MDM2-mediated ubiquitination and degradation, which then causes increased Ang-II and decreased NO in lung ECs contributing to the development and progression of PAH. Metformin, an activator of AMPK, induces AMPK-mediated ACE2 phosphorylation at S680 and protects ACE2 from MDM2-mediated ubiquitination, thereby exert therapeutic effect on PAH. In addition, given the specific binding of SARS-CoV-2 to ACE2, the AMPK/MDM2-mediated PTM of ACE2 may also be implicated in SARS-CoV-2-associated acute and chronic lung injury and acute respiratory distress syndrome.

Figure Legends

Figure 1. MDM2 level is elevated in PH. (A, B) In the network view, a node is positioned in the center of the canvas showing the putative substrates, surrounded by nodes revealing predicted E3 ligases. The node colors and characters denote the E3 ligase type with the edge width and node size representing the confidence score. In the confidence mode (A), both edge width and node size are positively correlated with the UbiBrowser score. In the evidence mode (B), the edge of each predicted E3-substrate interaction consists of multiple colored lines, with distinct colors representing different types of supporting evidences, including E3-recognizing motif (blue), network loops (black), and enriched GO pair (purple). (C) RNA-seq data for predicted E3 ligases in iPSC-derived ECs. The heatmap shows the expression of genes involved in familial PAH patients with BMPR2 mutation versus controls. (D, E) qPCR quantification of MDM2 mRNA levels and western blot analysis of MDM2 and ACE2 levels in lung tissue from IPAH patients (n=6) and controls without PAH (n=6). (F, G) qPCR quantification of MDM2 mRNA level and western blot analysis of MDM2 and ACE2 levels in PAECs isolated from IPAH (n=4) and control lungs (n=4). (H-K) qPCR quantification of MDM2 mRNA level and western blot analysis of MDM2 and ACE2 levels in the lung tissues of SuHx-induced PH mice (n=5) and control mice (n=5) (H, I) and MCT-induced PH rat models (n=9) vs. controls (n=9) (J, K). Data are mean \pm SEM. For data with normal distribution (D, H, and J), statistical significance was determined by two-tailed Student-*t* test with Welch correction between 2 indicated groups. Non-normally distributed data (E, F, G, I and K) were analyzed using Mann-Whitney U test between 2 indicated groups. **p*<0.05 vs. control patients (Ctrl) or Normoxia (Nor) or vehicle (Veh) controls.

Figure 2. MDM2 decreases ACE2 stability via ubiquitination. (A-C) Western blot analysis of ACE2 and MDM2 levels in PAECs transfected with MDM2 or control siRNA (20 nM) for 48 hr (A); JNJ-165 (10 μ M) or vehicle for 16 hr (B); and MDM2 overexpression or control plasmid (1 μ g/ml) in BAECs for 48 hr (C). (D, E) Western blot analysis of ACE2 in HEK293 cells transfected with MDM2 siRNA (20 nM), MDM2 overexpression plasmids (MDM2-WT), or MDM2 RING domain mutation plasmids (MDM2-C464A) together with ACE2 overexpression plasmids (1 μ g/ml), then treated with CHX (100 μ g/ml) for up to 8 hr. (F) HEK 293 cells were co-transfected with ACE2 and Ubiquitin (Ub) overexpression plasmids (1 μ g/ml) and were treated with MG132 (20 μ M) 10 hr before harvesting the cells. Separately, HEK293 cells were treated with JNJ-165 (10 μ M) or vehicle for 16 hr before harvesting (a). HEK 293 cells were treated with MDM2 or control siRNA (20 nM) and cultured under normal or hypoxia condition (b, c) for 24 hr. Cell extracts were immunoprecipitated with anti-ACE2 or IgG and immunoblotted with anti-Ub. The input proteins were immunoblotted with antibodies against ACE2, MDM2, or α -tubulin. (G) HEK 293 were transfected with plasmids overexpressing ACE2 or MDM2 (1 μ g/ml). (H) HUVECs were treated with MG132 (20 μ M) for 10 hr. ACE2 or MDM2 was immunoprecipitated. The input protein was immunoblotted with antibodies against ACE2, MDM2, α -tubulin, or GAPDH. Data are mean \pm SEM from 3-4 independent experiments. Normally distributed data (B) were analyzed by two-tailed Student-*t* test with Welch correction between 2 indicated groups and normally distributed data (D, E) were analyzed by two-way ANOVA test between multiple groups. Non-normally distributed data (A, C) were analyzed using Mann-Whitney U test between 2 indicated groups. **p*<0.05 vs. controls (Ctrl) or control-siRNA (Ctrl-siR).

Figure 3. MDM2 ubiquitinates ACE2 at K788. (A) Schematic diagram showing the functional domains as well as S680 and K788 of ACE2, which are conserved among human, mouse, and rat. (B) HEK293 cells were transfected with expression plasmids encoding ACE2-S680D, ACE2-S680L, or ACE2-S680L/K788R (ACE2-R) together with Ub plasmids (1 μ g/mL) and MG132 (20 μ M) treatment in the last 10 hr. Cell lysates were immunoprecipitated by anti-ACE2 or IgG, then immunoblotted with anti-Ub. The input proteins were immunoblotted with anti-ACE2 or anti- α -tubulin. (C) HEK293 cells were transfected with ACE2-S680L or ACE2-S680L/K788R together with Ub plasmids (1 μ g/mL) under hypoxia or normoxia for 24 hr with MG132 (20 μ M) treatment in the last 10 hr. Ubiquitination of various forms of ACE2 was analyzed. (D) Western blot analysis of ACE2 and α -tubulin in HEK293 cells transfected with ACE2-S680L or ACE2-S680L/K788R (ACE2-R) plasmids, then treated with CHX for 0, 4, and 8 hr. (E) HEK293 cells were transfected with ACE2-WT, ACE2-S680D, ACE2-S680L, or ACE2-S680L/K788R (ACE2-R), together with and eNOS expression plasmids (1 μ g/mL). Cell lysates were immunoblotted with antibodies against peNOS (S1177), peNOS (T495), eNOS, ACE2, ACE1, or α -tubulin. (F) PAECs were infected with ACE2-WT, ACE2-S680D, ACE2-S680L, and ACE2-S680L/K788R adenovirus (10 MOI). Cell lysates were immunoblotted with antibodies against peNOS (S1177), peNOS (T495), eNOS, ACE2, ACE1, or α -tubulin. (G) ELISA assay of Ang 1-7 in PAECs infected with ACE2-WT, ACE2-S680D, ACE2-S680L, and ACE2-S680L/K788R adenovirus (10 MOI). Data are mean \pm SEM from 3-9 independent experiments. Normally distributed data (G) were analyzed by one-way ANOVA test between multiple groups and normally distributed data (D) were analyzed by two-way ANOVA test between multiple groups. Non-normally distributed data (E, F) were analyzed using Kruskal-Wallis test between multiple groups. * p <0.05 vs. WT, # p <0.05 vs. L and R.

Figure 4. MDM2 inhibition alleviates experimental PH in mice. (A) Eight-week-old C57BL/6 mice were subjected to normoxia (Nor) or SuHx (10% O₂ with subcutaneous injection of SU5416 at 20 mg/kg /week) for 5 weeks. Nor and SuHx mice were administered with vehicle (Veh) or JNJ-165 (20 mg/kg/d) during the last 2 weeks by oral gavage. (B, C) Summarized data (mean ± SEM) showing right ventricular systolic pressure (RVSP, B) and Fulton Index [RV/(LV+S), C] in Nor and SuHx mice treated with Veh or JNJ-165. (D) H&E staining of pulmonary arteries (left panels) and summarized data (mean ± SEM, right panel) showing the pulmonary arterial (PA) wall thickness from Nor+Veh, SuHx+Veh, and SuHx+JNJ-165 mice. Scale bar = 20 μm. (E) Representative lung angiogram (left panels) of the left lungs at 8× (upper panels) and 30× (lower panels) magnification from Nor+Veh, SuHx+Veh, and SuHx+JNJ-165 mice. Summarized data (mean ± SEM, n=4 lungs, right panels) showing the total length of branches, number of branches, and number of junctions of the left lungs from Nor+Veh, SuHx+Veh, and SuHx+JNJ-165 mice. (F) Western blot analysis (left panel) of eNOS phosphorylation at S1176 and T494, eNOS, ACE2, and MDM2, along with summarized data (mean ± SEM, right panels) showing the expression levels of peNOS (S1176), peNOS(T494), ACE2, and MDM2, in lung tissues from Nor+Veh, SuHx+Veh, or SuHx+JNJ-165 mice. (G, H) qPCR analysis of endothelin-1 (END1), angiotensin 1 (ANGPT1), prostacyclin synthase (PTGIS) and bone morphogenetic protein receptor II (BMP2) mRNAs (G); vascular cell adhesion molecule 1 (VCAM-1), vascular endothelial growth factor (VEGF), platelet derived growth factor subunit A (PDGFA), interleukin 6 (IL-6), monocyte chemoattractant protein-1 (MCP-1), and interleukin 1β (IL-1β) (H) in lung tissues from Nor+Veh, SuHx+Veh, and SuHx+JNJ-165 mice. Data are mean ± SEM (7-9 mice per group). Normally distributed data (B, C, D and G) were analyzed by one-way ANOVA test between multiple groups. Non-normally

distributed data (E, F) were analyzed using Kruskal-Wallis test between multiple groups.

* $p < 0.05$ vs. Nor+Veh; # $p < 0.05$ vs. SuHx+Veh.

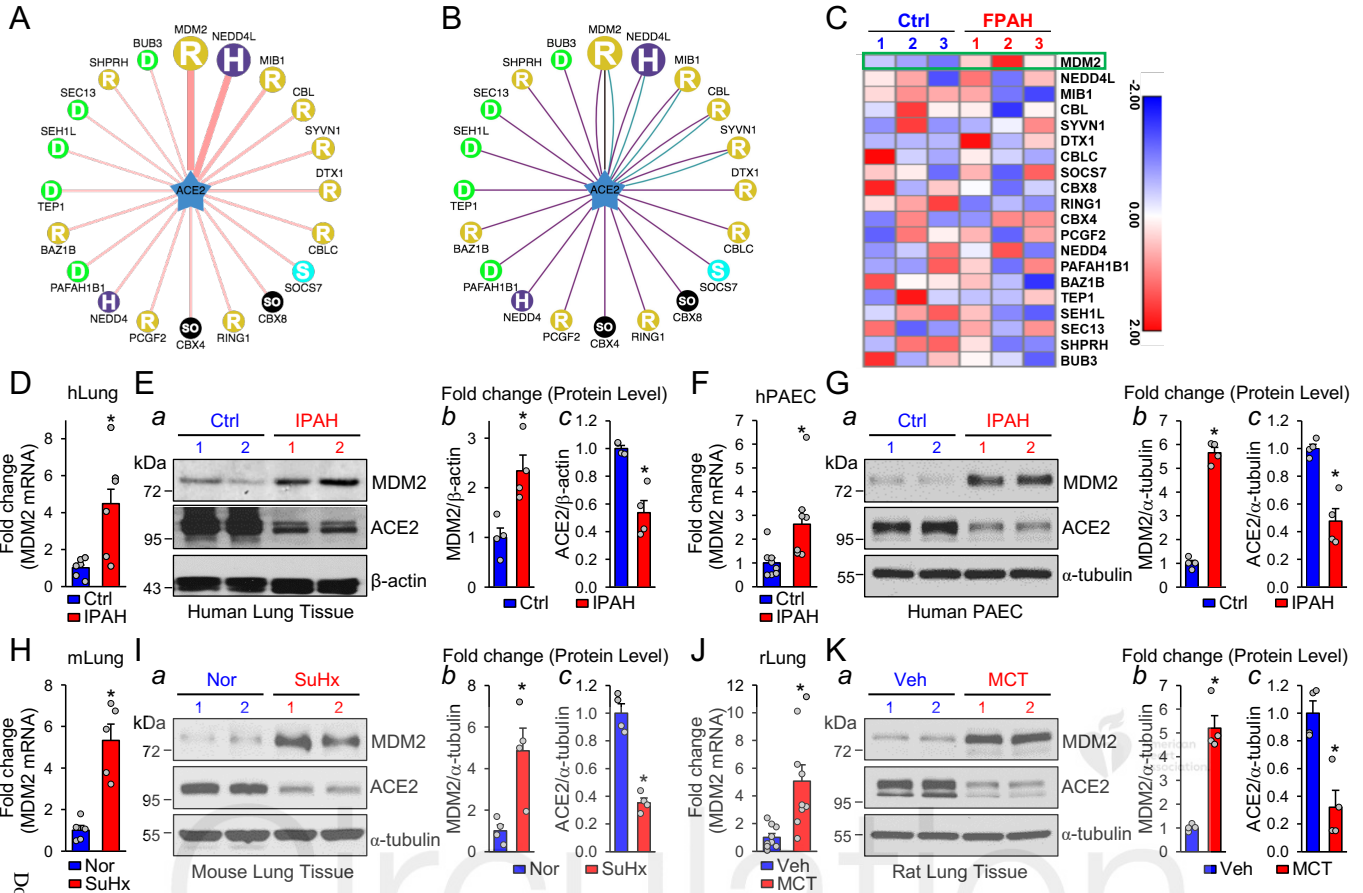

Figure 5. ACE2-K788R alleviates PH in ACE2-S680L mice. (A) Eight-week-old ACE2-S680D (ACE2-D) and ACE2-S680L (ACE2-L) mice were subjected to normoxia or SuHx for 5 weeks. The SuHx-treated mice were administrated adenoviral-null (Ad-N) or adenoviral-ACE2-S680L/K788R (Ad-R) intratracheally at the beginning of the experiments. (B, C) Summarized data (mean \pm SEM) showing RVSP (B) and Fulton Index [RV/(LV+S), C] in normoxic (Nor) ACE2-D and ACE2-L mice and SuHx-treated ACE2-D and ACE2-L mice receiving Ad-N or Ad-R. (D) Histological images with H&E staining of pulmonary arteries (left panels) and summarized data (mean \pm SEM, right panel) showing the pulmonary arterial (PA) wall thickness from Nor+ACE2-D, Nor+ACE2-L, SuHx+ACE2-D+Ad-N, SuHx+ACE2-L+Ad-N, or SuHx+ACE2-L+Ad-R mice. Scale bar = 20 μ m. (E) Western blot analysis (left panel) of peNOS S1176 or T494, eNOS, ACE2 and MDM2, along with summarized data (mean \pm SEM, right panels) showing the expression levels of peNOS S1176, peNOS T494, ACE2, and MDM2, in lung tissues from SuHx+ ACE2-D+Ad-N, SuHx+ACE2-L+Ad-N or SuHx+ACE2-L+Ad-R mice. (F) qPCR analysis of END1, ANGPT1, PTGIS, and BMP2 mRNA in lung tissues from Nor+ACE2-D, Nor+ACE2-L, SuHx+ ACE2-D+Ad-N, SuHx+ACE2-L+Ad-N, or SuHx+ACE2-L+Ad-R mice. Data are mean \pm SEM (5-9 mice per group). Normally distributed data (B, C, D and F) were analyzed by one-way ANOVA test between multiple groups. Non-normally distributed data (E) were analyzed using Kruskal-Wallis test between multiple groups. * $p < 0.05$ vs. Nor+ACE2-L; # $p < 0.05$ vs. SuHx+ACE2-L+Ad-N; * $p < 0.05$ between SuHx+ACE2-D+Ad-N and SuHx+ACE2-L+Ad-N as indicated.

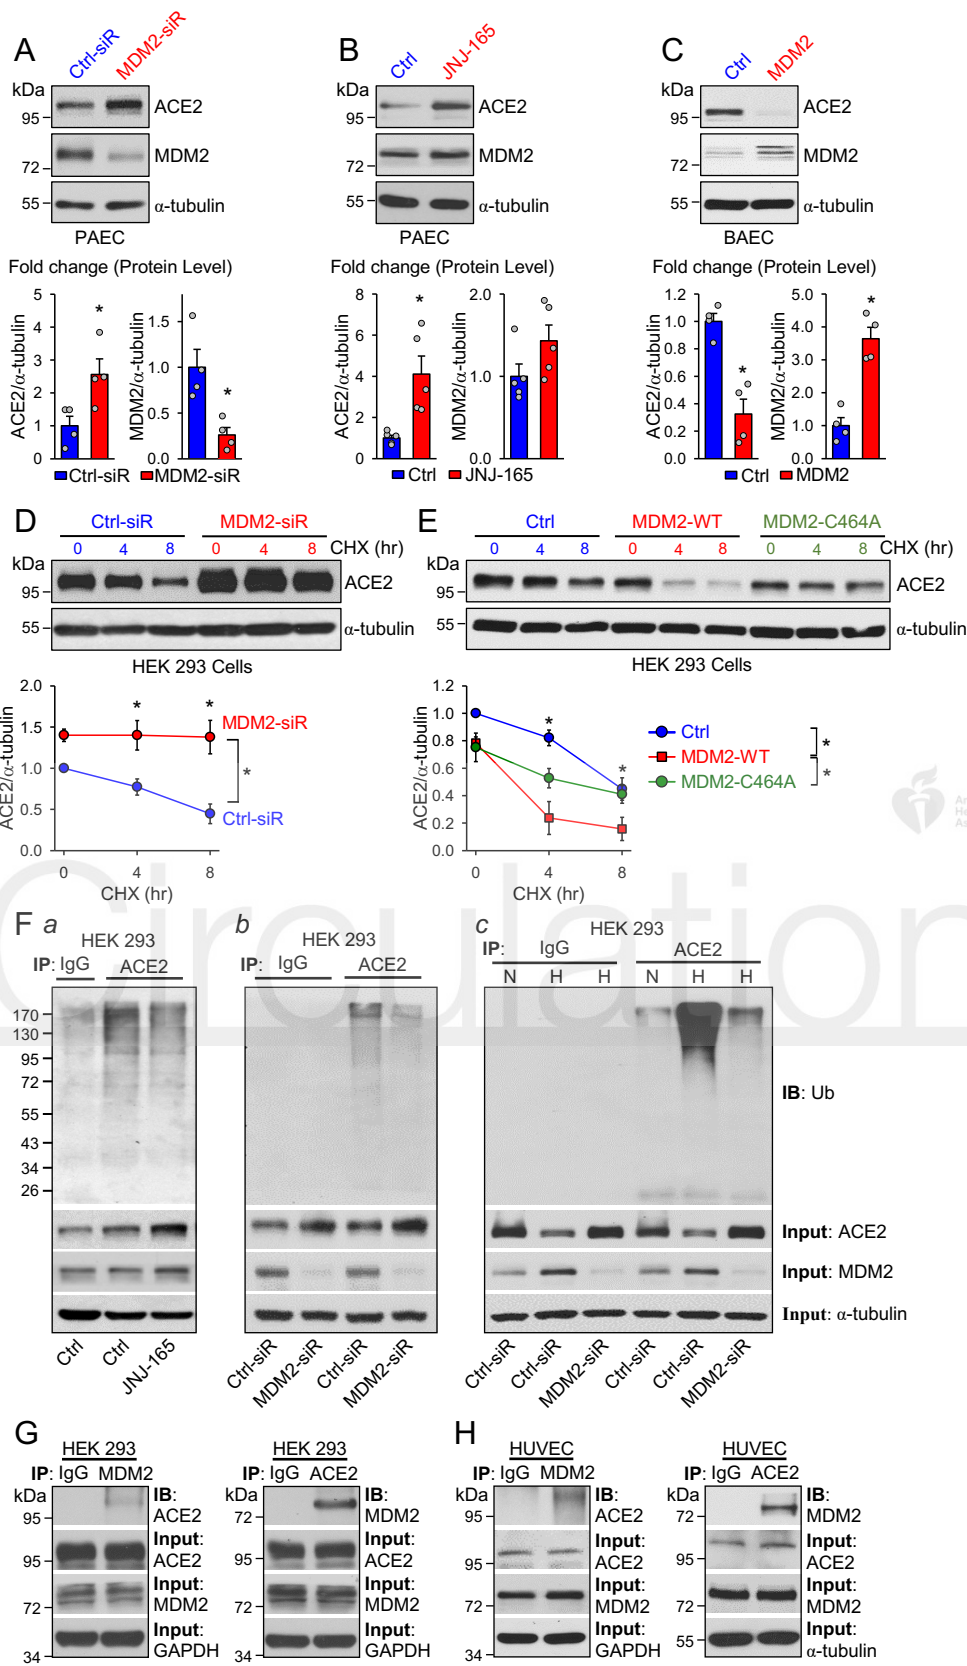

Figure 6. ACE2-K788R ameliorates PH in EC-AMPK α 2^{-/-} mice. Eight-week-old EC-AMPK α 2^{-/-} mice were subcutaneously injected with SU5416 and exposed to hypoxia (10% O₂) for 3 weeks before adenoviral infection was introduced intratracheally; the hemodynamic, histological and angiogram measurements were conducted in the mice two weeks after adenoviral infection. **(A)** Representative records of right ventricular pressure (RVP) (*a*), summarized RVSP (*b*), and estimated mean pulmonary arterial pressure (mPAP, calculated by the equation: mPAP = 0.6RVSP+2 mmHg, (*c*) in normoxic mice receiving adenovirus null (Nor-Ad-N) and SU5416/Hypoxia (SuHx)-treated mice with adenoviral null (SuHx+Ad-N) or adenoviral infection of wild-type ACE2 (SuHx-ACE2-WT) and ACE2-K788R (SuHx+ACE2-R). Representative RV- \pm dp/dt (*d*) and summarized values of RV- \pm dp/dt_{max} (*e*, mean \pm SEM) from Nor-Ad-N, SuHx+Ad-N, SuHx+ACE2-WT and SuHx+ACE2-K788R mice are also shown. (*f*) shows averaged heart rate in Nor+Ad-N, SuHx+Ad-N, SuHx+ACE2-WT and SuHx+ACE2-K788R mice. **(B)** Histological images with H&E staining of pulmonary arteries (*a*) and summarized data (mean \pm SEM) showing the pulmonary arterial (PA) wall thickness (*b*) from Nor+Ad-N, SuHx+Ad-N, SuHx+ACE2-WT, and SuHx+ACE2-K788R mice. Scale bar = 20 μ m **(C)** Representative lung angiogram (*a*) of the left lung at 8 \times (upper panels) and 30 \times (lower panels) magnification from Nor+Ad-N, SuHx+Ad-N, SuHx+ACE2-WT, and SuHx+ACE2-K788R mice. Summarized data (mean \pm SEM, n=5 mouse lungs, *b*) showing the total length of branches (left panel), number of branches (middle panel) and number of junctions (right panel). **(D)** Fulton index, the ratio of the weight of right ventricle (RV) to the weight of left ventricle (LV) and septum (S) ([RV/LV+S]), in Nor+Ad-N, SuHx+Ad-N, SuHx+ACE2-WT and SuHx-ACE2-K788R mice. **(E)** Immunoprecipitation (IP) and western blot analyses (left panel) on Ub, peNOS at S1176 and T494, eNOS, ACE2 and MDM2, along with summarized data (mean \pm

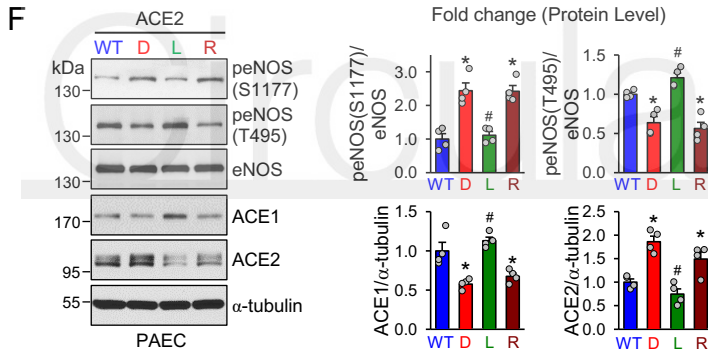

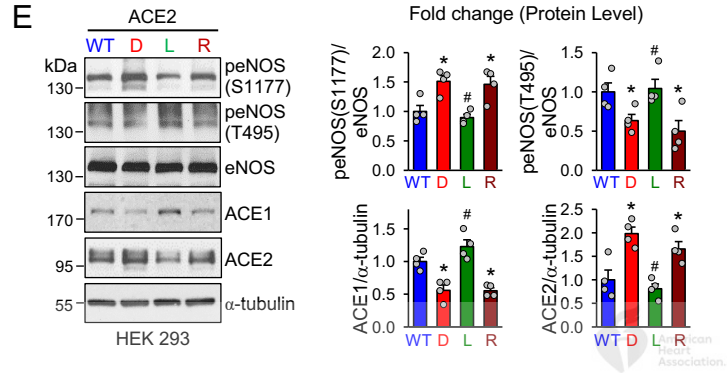

SEM) showing the expression levels of peNOS S1176, peNOS T494, ACE2 and MDM2, in lung tissues from Nor+Ad-N, SuHx+Ad-N, SuHx+ACE2-WT and SuHx+ACE2-R mice. (F) qPCR analysis of END1, ANGPT1, PTGIS, and BMPR2 transcripts in lung tissues from Nor+Ad-N, SuHx+Ad-N, SuHx+ACE2-WT and SuHx+ACE2-R mice. Data are mean \pm SEM (6-10 mice per group). Normally distributed data (A, B and D) were analyzed by one-way ANOVA test between multiple groups. Non-normally distributed data (C, E and F) were analyzed using Kruskal-Wallis test between multiple groups. * p <0.05 vs. Nor+Ad-N; # p <0.05 vs. SuHx+Ad-N and SuHx+ACE2-WT.

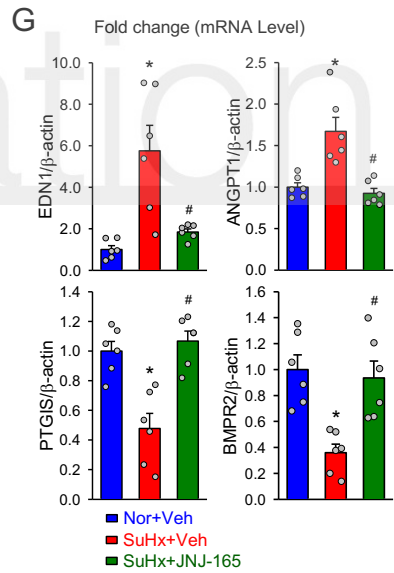

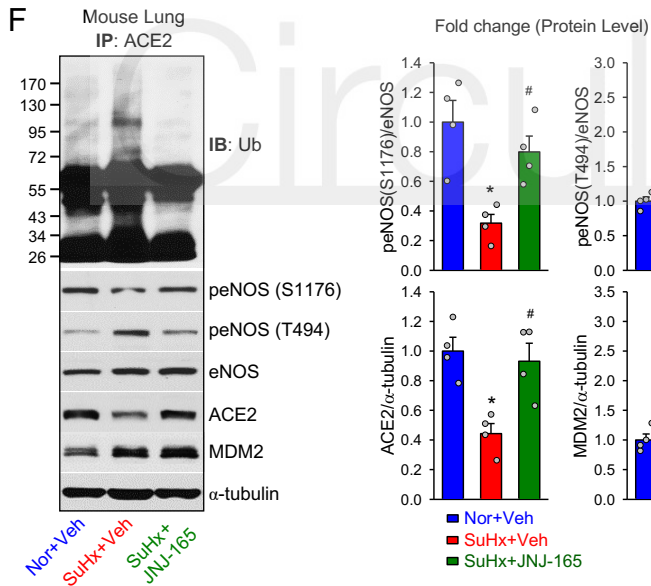

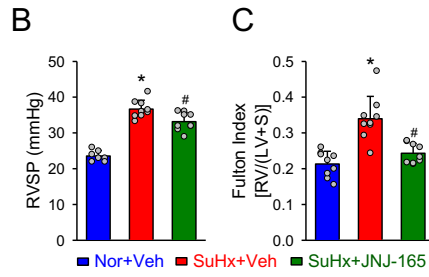

Figure 7. Schematic illustration of AMPK and MDM2-modulated the phosphorylation and ubiquitination of ACE2 in PAH. In functional pulmonary endothelial cells or those under

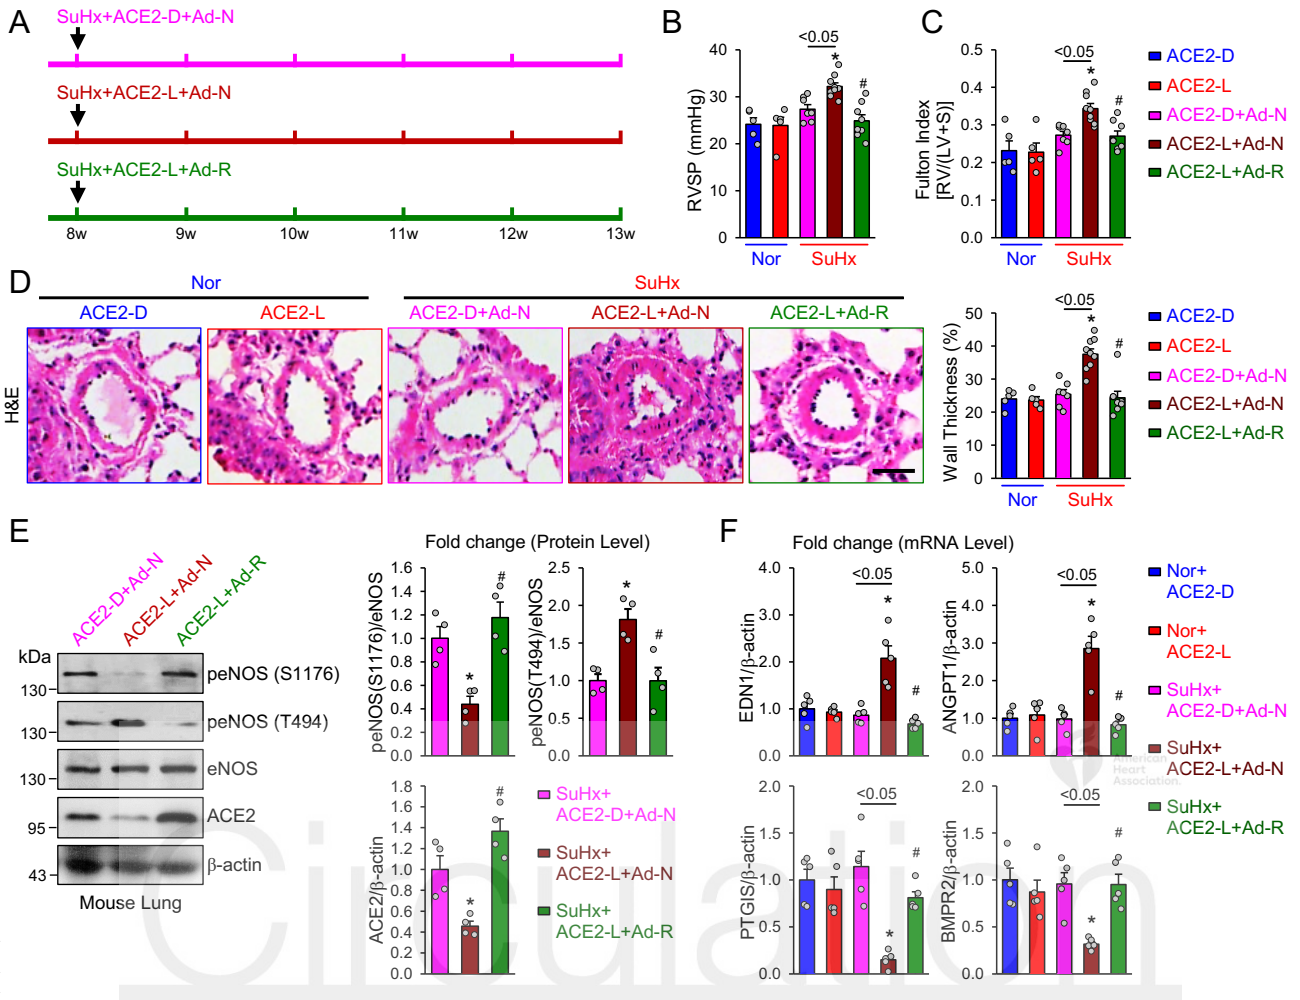

metformin therapy, AMPK phosphorylates ACE2 at S680 to increase its stability to maintain the eNOS-derived NO bioavailability. As an E3 ligase of ACE2, MDM2 ubiquitinates ACE2 at K788 resulting in its degradation under hypoxia, thereby inducing disorder of RAS system and dysfunction of ECs, eventually lead to PAH. Such pathological modulation may be reversed by JNJ-165 therapy, which inhibit the MDM2 E3 function.
